SWAP 4 simulates transport of water, solutes and heat in the vadose zone. It describes a domain from the top of canopy into the groundwater which may be in interaction with a surface water system. The program has been developed by Wageningen Environmental Research and Wageningen University, and is designed to simulate transport processes at field scale and during entire growing seasons. This is a new release with recent developments on atmosphere, soil water and crop growth interactions. This manual describes the theoretical background, model use, input requirements and output tables.

Keywords: agrohydrology, drainage, evaporation, irrigation, salinization, simulation model, soil water, solute transport, surface water management, transpiration, vadose zone

# Preface

The ecohydrological model SWAP has a history of more than 40 years. The first version (called SWATR) was developed by Reinder Feddes and colleagues in The Netherlands and published in 1978. During its history regularly updates were spread with derived acronyms SWATRE, SWACROP, SWAP93, and SWAP: Feddes et al. (1978); Belmans et al. (1983); Wesseling et al. (1991); Kabat et al. (1992); Van den Broek et al. (1994); Van Dam et al. (1997); Kroes et al. (2001; 2003; 2008). The last standard Internet version was published as SWAP3.2.36 by Kroes et al. (2009).

SWAP is used by researchers, engineers and students in the field of environmental science. Researchers employ the interactions between soil, water, plant and atmosphere as simulated by SWAP and the easy way in which the model can be adapted to specific research questions. Environmental engineers use the model as published and employ the practical boundary conditions of the model. In education SWAP is used to demonstrate typical transport situations in the biosphere. Students, ranging from Bachelor to PhD level, practice with the model. Some PhD students use SWAP as a research platform, to which they add innovative concepts.

At Wageningen University and Research centre fundamental and applied research are closely entangled. Scientists and students of various environmental disciplines and from all continents collaborate intensively. This creates much synergy, of which SWAP is one of the products.

Since the last release in 2009 a large number of new ideas have been tested with SWAP. Currently in environmental research much attention is paid to the food-water-energy nexus. In this research interaction between soil hydrology and crop growth plays a key role. In WaterVision Agriculture (Hack-ten Broeke et al., 2016; in Dutch: 'Waterwijzer Landbouw') we bring together the Dutch experience on how crop growth is affected by soil, climate and stresses due to lack of oxygen, lack of water or due to excess of salts. In the frame of WaterVision Agriculture we release this new SWAP version in which we implemented versatile improvements of recent years.

Our exciting journey does not end here. The future will bring new challenges. Therefore we supply SWAP with a well-structured source code and invite users to implement and test their own ideas. We very much appreciate feedback on the use of SWAP and suggestions for further improvements.

The SWAP team  
Wageningen, May 2017

---

# Summary

SWAP (Soil-Water-Atmosphere-Plant) simulates transport of water, solutes and heat in the vadose zone in interaction with vegetation development. In the vertical direction the model domain reaches from a plane just above the canopy to a plane in the shallow groundwater. In this zone the transport processes are predominantly vertical, therefore SWAP is a one-dimensional, vertically directed model. In the horizontal direction, SWAP's main focus is the field scale.

The SWAP model can be downloaded from site [www.swap.alterra.nl](http://www.swap.alterra.nl). The model input may consist of files for main input, meteorological data, crop growth and drainage. SWAP employs the TTUTIL library to read the ASCII input files in easy format. Output is generated in ASCII and binary files. The internet site contains a large number of SWAP applications in scientific literature (Chapter 1).

Soil water flow is calculated with the Richards equation. The Mualem-Van Genuchten relations, with a modification near saturation, describe the soil hydraulic functions. Scaling of main drying and wetting curves is used to describe hysteresis in the retention function. The bottom boundary is controlled by head, flux or the relation between flux and head. SWAP solves the Richards equation numerically with an implicit, backward, finite difference scheme. The Newton-Raphson iterative procedure ensures mass conservation and rapid convergence (Chapter 2).

For agricultural crops and grassland, SWAP computes the interception following Von Hoyningen-Hüne and Braden. The interception concept of Gash is available for forests. The Penman-Monteith equation can be used to calculate the potential evapotranspiration of uniform surfaces (wet and dry vegetation, bare soil). An alternative is providing input of reference evapotranspiration in combination with crop factors. Next the potential transpiration and evaporation fluxes of partly covered soils are derived, taking into account interception and soil cover. Actual transpiration depends on the moisture and salinity conditions in the root zone, weighted by the root density. Actual evaporation depends on the capacity of the soil to transport water to the soil surface. SWAP uses the soil hydraulic functions and semi-empirical equations to determine this transport capacity (Chapter 3).

Surface runoff will be calculated when the height of water ponding on the soil surface exceeds a critical depth. The rate of surface runoff depends on a specified resistance. Interflow may occur when the groundwater level becomes higher than the interflow drainage level. Drainage can be calculated with the Hooghoudt or Ernst equations, with a table relating drainage flux and groundwater level, or with drainage resistances per drainage system. In order to calculate proper residence times of solutes, the drainage fluxes are vertically distributed according to so-called discharge layers (Chapter 4). The water balance of the surface water system can be calculated to analyse water management options. Surface water levels can be imposed, or derived by setting soil moisture criteria (groundwater level, pressure head, minimum storage) in combination with a weir (Chapter 5).

Macroporosity can be caused by shrinking and cracking of soil, by plant roots, by soil fauna, or by tillage operations. The macropore module in SWAP includes infiltration into macropores at the soil surface, rapid transport in macropores to deeper layers, lateral infiltration into and exfiltration out of the soil matrix, water storage in macropores, and rapid drainage to drainage systems. The macropores are divided in a main bypass domain (network of continuous, horizontal interconnected macropores) and an internal catchment domain (discontinuous macropores ending at different depths). The internal catchment domain causes infiltration of macropore water at different, relatively shallow depths. In addition, the macropores are divided in static and dynamic volumes. The dynamic volumes depend on shrinkage characteristics (Chapter 6).

The simple crop module prescribes crop development, independent of external stress factors. Its main function is to provide a proper upper boundary condition for soil water movement. In addition, SWAP includes the generic crop growth module WOFOST. In this module, the absorbed radiation is a function of solar radiation and crop leaf area. Next the produced carbohydrates ( $\text{CH}_2\text{O}$ ) are calculated, taking into account photosynthetic leaf characteristics and possible water and/or salinity stress. The carbohydrates provide energy for living biomass (maintenance respiration) and are converted into structural material during which weight is lost as growth respiration. The material produced is partitioned among roots, leaves, stems and storage organs, using partitioning factors that depend on the crop development stage. The fraction partitioned to the leaves, determines leaf area development

---

and hence the dynamics of light interception. During crop development a part of the living biomass dies due to senescence (Chapter 7).

Grass growth is special: it is perennial, very sensitive to nitrogen, and grass is either grazed or mowed. Therefore SWAP includes a separate WOFOST module for grass, which simulates these special grass features (Chapter 7).

SWAP simulates transport of salts, pesticides and other solutes that can be described with basic physical relations: convection, diffusion, dispersion, root uptake, Freundlich adsorption and first order decomposition. In case of advanced pesticide transport, including volatilization and kinetic adsorption, SWAP can be used in combination with PEARL. In case of advanced transport of nitrogen and phosphorus, SWAP can be used in combination with ANIMO or Soil-N (Chapter 8).

SWAP may simulate soil temperature analytically, using an input sine function at the soil surface and the soil thermal diffusivity. In the numerical approach, SWAP takes into account the influence of soil moisture on soil heat capacity and soil thermal conductivity. The top boundary condition may include air temperatures or soil surface temperatures (Chapter 9).

The snow module calculates the accumulation and melting of a snowpack when the air temperature is below a threshold value. The water balance of the snow pack includes storage, incoming snow and rain and outgoing melting and sublimation. Melting may occur due to air temperature rise or heat release from rainfall. When a snowpack is present, the soil temperature top boundary condition is adjusted in order to account for the insulating effect of the snowpack. In case of frost, reduction factors can be calculated for the hydraulic conductivity, root water uptake, drainage fluxes and bottom flux (Chapter 10).

Irrigations with fixed date, depth and quality can be specified as input. In addition, SWAP can be used to schedule and optimize irrigation. Timing criteria include allowable daily stress, allowable depletion amount and critical pressure head or water content. Depth criteria include back to field capacity and fixed depth (Chapter 11).

The SWAP installation file includes cases which can be run directly after extraction. Chapter 12 describes the context and results of the following cases:

1. HupselBrook (typical Dutch field with subsurface drains and crop rotation),
2. GrassGrowth (growth and yield of a Dutch grassland field in Ruurlo),
3. MacroporeFlow (field experiment where macro pore flow occurs, Andelst),
4. OxygenStress (grassland field with shallow groundwater and oxygen stress),
5. SalinityStress (potato crop under saline conditions, saltFarm, Texel),
6. SurfaceWater (surface water management in a rural estate Wildenborch).

Most cases include one or more R-procedures (R, 2013) to graphically display some model results. Observations are sometimes included to have reference points during visual comparisons with simulation results.

The appendices contain information on the parameters of the soil hydraulic functions, critical pressure heads for root water extraction, salt tolerance data, shrinkage characteristic data, numerical solution of water and heat flow, contents of binary output files and names of the main SWAP subroutines.

# 1 Model overview

## 1.1 Model domain and processes

SWAP simulates transport of water, solutes and heat in the vadose zone in interaction with vegetation development. The model employs the Richards equation including root water extraction to simulate soil moisture movement in variably saturated soils. In addition to ordinary matrix flow, SWAP considers flow through macropores as may occur in clay and peat soils. Solute transport includes the basic processes convection, dispersion, adsorption and decomposition. For more detailed solute transport studies, SWAP can be used in combination with specialized chemical transport models such as PEARL for pesticides and Soil-N or ANIMO for nitrogen. SWAP simulates soil heat flow taking into account actual heat capacities and thermal conductivities. The generic crop growth module WOFOST is incorporated to simulate leaf photosynthesis and plant growth. The soil moisture, heat and solute modules exchange status information each time step to account for their interactions. On a daily basis crop growth is affected by actual conditions of weather, soil moisture and salinity. An extensive test protocol ensures the numerical code quality of SWAP.

**Figure 1.1** SWAP model domain and transport processes.

In the vertical direction the model domain reaches from a plane just above the canopy to a plane in the shallow groundwater (Figure 1.1). In this zone the transport processes are predominantly vertical, therefore SWAP is a one-dimensional, vertical directed model. The flow below the groundwater level may include lateral drainage fluxes, provided that these fluxes can be prescribed with analytical drainage formulas. The model is very flexible with respect to input data at the top and bottom of the soil column. At the top in general daily weather conditions will suffice. For Nordic conditions a simple snow storage module has been implemented. In case of more focussed studies (e.g. runoff or diurnal transpiration fluxes) evapotranspiration and rainfall data can be specified in more detail. At the bottom various forms of head and flux based conditions are used.

In the horizontal direction, SWAP's main focus is the field scale. At this scale most transport processes can be described in a deterministic way, as a field generally can be represented by one microclimate, one vegetation type, one soil type, and one drainage condition. Also many cultivation practices occur at field scale, which means that many management options apply to this scale. Upscaling from field to regional scale for broader management policy studies is possible with geographical information systems.

The smallest time steps in SWAP are in the order of seconds for fast transport processes such as intensive rain showers with runoff or flow in macroporous clay soils. These time steps are automatically increased in periods with more slow flow conditions. Depending on simulation complexity, computation times for 50 year periods range from 30 to 500 seconds on ordinary personal computers.

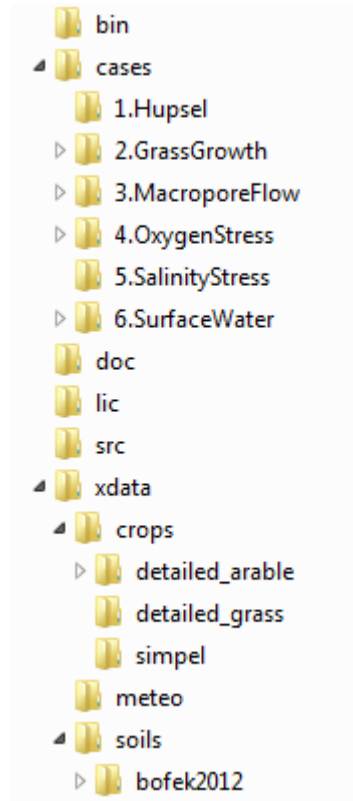

## 1.2 SWAP installation

The SWAP model can be downloaded from Internet site [www.swap.alterra.nl](http://www.swap.alterra.nl). This site contains general information on model features, applications and test reports. Various SWAP versions are available at the Internet site. This manual applies to SWAP 4. Only the most recent SWAP version is supported by the Swap team.

To allow installation on different operating system, we compiled a versatile set for distribution and packed all files into one zip-file. The zip-file can be unpacked on an arbitrary folder. Once unpacked a number of subfolders are created (Figure 1.2), which contain:

- Swap executable
- Swap source code
- User manual
- Several case studies
- Additional input data:
  - Daily weather data of Wageningen meteorological station of the period 1971-2000.
  - Simple crop input data for grass, fodder maize, potato, sugar beet and winter wheat.
  - Detailed crop input data for winter wheat, grain maize, spring barley, rice, sugar beet, potato, field bean, soy bean, winter oilseed rape and sunflower.

SWAP can be automatically launched for the example Hupsel. Also runs can be made with the other 5 case studies described in Chapter 12.

**Figure 1.2** Installed folders by standard SWAP installation.

## 1.3 Model input

The input data of SWAP are divided over 4 different file types:

- Main input file (\*.swp)
- Meteorological file (\*.yyy)
- Crop growth file (\*.crp)
- Drainage file (\*.dra)

Box 1.1 provides an overview of the information in these input files. The main input file and the meteorological data file are always required. Input files of crop growth and drainage are optional. The extensions of the files are fixed. An exception is the meteorological file, which has an extension equal to the last 3 digits of the year (e.g. 2017 gives .017). The names of the input files are free to choose and are specified in the main input file. As listed in Box 1.1, the main input file contains general information with regard to the simulation, meteorology, crop rotation scheme, irrigation, soil water flow, heat flow and solute transport. For meteorological data, commonly a file with daily data is used. In Chapter 3 also more detailed input of evapotranspiration and rainfall fluxes will be discussed. The detailed crop growth input file is required to simulate crop development and biomass assimilation. As an alternative, the development of crop parameters as leaf area index or rooting depth can be

prescribed in the simple crop growth input file. The drainage input file contains two sections. The first, basic drainage section provides input for drainage towards ditches and/or drains. The second, extended drainage section provides input for drainage including simulation of surface water levels.

Box 1.1 Summary of information in input files. Optional files are denoted with #.

**Main input file (\*.swp)**

- *General section*
  - Environment
  - Timing of simulation period
  - Timing of boundary conditions
  - Processes which should be simulated
  - Optional output files
- *Meteorology section*
  - Name of file with meteorological data
  - Rainfall intensity
- *Crop section*
  - Crop rotation scheme (calendar and files)
  - Crop data input file
  - Calculated irrigation input file
  - Crop emergence and harvest
  - Fixed irrigation parameters (Amount and quality of prescribed irrigation applications)
- *Soil water section*
  - Initial moisture condition
  - Ponding
  - Soil evaporation
  - Vertical discretization of soil profile
  - Soil hydraulic functions
  - Hysteresis of soil water retention function
  - Maximum rooting depth
  - Similar media scaling of soil hydraulic functions
  - Preferential flow due to soil volumes with immobile water
  - Preferential flow due to macro pores
  - Snow and frost
  - Numerical solution of Richards' equation
- *Lateral drainage section*
  - (optional) name of file with drainage input data
  - (optional) name of file with runoff input data
- *Bottom boundary section*
  - (optional) name of file with bottom boundary conditions
  - selection out of 8 options
- *Heat flow section*
  - calculation method
- *Solute transport section*
  - Specify whether simulation includes solute transport or not
  - Top boundary and initial condition
  - Diffusion, dispersion, and solute uptake by roots
  - Adsorption
  - Decomposition
  - Transfer between mobile and immobile water volumes (if present)
  - Solute residence in the saturated zone

**File with daily meteorological data (\*.yyy)**

- Radiation, temperature, vapour pressure, wind speed, rainfall and/or reference evapotranspiration,
- rainfall intensities

SWAP uses the TTUTIL library (Kraalingen & Rappoldt, 2000) for reading input files. Box 1.2 gives an example of a part of the \*.swp input file. General rules for the format of input files are:

- free format with the structure 'VariableName' = 'value' or, in case of arrays, in a table with variable names in the first line;
- order of variables is free;
- comment in lines is allowed starting with symbols '\*' or '!';
- blank lines are allowed.

The input files list of each parameter their symbolic name, a description and an identification. The identification between square brackets provides information on:

- the range
- the unit
- the data type (I = Integer, R = Real, Ax = character string of x positions)

For example: [-5000 .. 100 cm, R] means: value between -5000 and +100 with a unit in cm, given as a Real data type (which means that the value in the input file should contain a dot).

Box 1.2 Example of input according to TTUTIL in main file \*.SWP.

```
* File name
METFIL = 'Hupsel' ! File name of meteorological data without extension .YYY, [A200]
                ! Extension is equal to last 3 digits of year, e.g. 003 denotes year 2003

* Type of weather data for potential evapotranspiration
SWETR = 0        ! 0 = Use basic weather data and apply Penman-Monteith equation
                ! 1 = Use reference evapotranspiration data in combination with crop factors

* If SWETR = 0, specify:
LAT    = 52.0    ! Latitude of meteo station [-90..90 degrees, R, North = +]
ALT    = 10.0    ! Altitude of meteo station [-400..3000 m, R]
ALTW   = 10.0    ! Height of wind speed measurement above soil surface (10 m is default) [0..99 m, R]
ANGSTROMA = 0.25 ! Fraction of extraterrestrial radiation reaching the earth on overcast days [0..1 -, R]
ANGSTROMB = 0.50 ! Additional fraction of extraterrestrial radiation on clear days [0..1 -, R]

* Time interval of evapotranspiration and rainfall weather data
SWMETDETAIL = 0    ! 0 = time interval is equal to one day
                ! 1 = time interval is less than one day

* In case of detailed meteorological weather records (SWMETDETAIL = 1), specify:
NMETDETAIL = 10    ! Number of weather data records each day [1..96 -, I]

* In case of daily meteorological weather records (SWMETDETAIL = 0):
SWETSINE = 0        ! Switch, distribute daily Tp and Ep according to sinus wave [Y=1, N=0]

SWRAIN = 0          ! Switch for use of actual rainfall intensity (only if SWMETDETAIL = 0):
                ! 0 = Use daily rainfall amounts
                ! 1 = Use daily rainfall amounts + mean intensity
                ! 2 = Use daily rainfall amounts + duration
                ! 3 = Use detailed rainfall records (dt < 1 day), as supplied in separate file

* If SWRAIN = 1, specify mean rainfall intensity RAINFLUX [0.d0..1000.d0 mm/d, R]
* as function of Julian time TIME [0..366 d, R], maximum 30 records
    TIME    RAINFLUX
    1.0      20.0
    360.0    40.0
* End of table
```

SWAP will read times according to the following format: 10-feb-2017\_16:30:00.00 denotes February 10, 2017 at 4.30 PM. If in the input only dates and no times are specified, SWAP will assume time 0:00. In case of input data series as function of time (e.g. groundwater levels) or depth (e.g. initial pressure heads), SWAP will apply linear interpolation for times and depths in between. Outside the specified range, the closest value will be adopted. For instance in Box 1.2, the rainfall intensity (RAINFLUX) will gradually increase from 20 to 40 mm d<sup>-1</sup> between t = 1.0 and t = 360.0 d. At t > 360.0 d, the rainfall intensity will be 40 mm d<sup>-1</sup>.

---

## 1.4 Model run

The most common way to run SWAP is by executing a batch file, which refers to the SWAP executable and the main input file \*.swp. The batch file and the \*.swp file need to be present in the same directory. The \*.swp file contains the names and locations of other input files. In this way the meteorological, crop and drainage data can be specified on separate folders.

An example of the batch file is given in Box 1.3. In this case SWAP will use Hupsel.swp as main input file. If no name is specified behind the executable call, SWAP assumes 'Swap.swp' as main input file. The pause statement keeps the window box with screen messages open; this is convenient when runtime warnings or errors occur.

Box 1.3 Example of batch file to run SWAP with input file Hupsel.swp.

```
c:\Program Files\SWAP\Swap.exe Hupsel.swp  
pause
```

An alternative to run SWAP is by double clicking file Swap.exe. In that case the main input file should be called 'Swap.swp', and should be located in the same folder as file Swap.exe.

Three types of messages may occur during a model run:

- error messages with respect to the input data
- warnings with the advise to adapt the combination of selected options because the specified combination is not feasible
- fatal calculation errors which stop the simulation

Output files will be generated in the same directory as the main input file. Here also the log file named '\*\_Swap.log' can be found. This log file contains a copy of the \*.swp file, possible errors and warnings, and in case of a successful simulation run the statement: 'Swap simulation okay!'

Box 1.4 Summary of information in output files. Optional files are denoted with #.

**Short water and solute balance (\*.bal)**

Final and initial water and solute storage  
Water balance components  
Solute balance components

## 1.5 Model output

Output from SWAP is stored in general ASCII files, which can be read with any editor or word processor. You may open the output file directly in Excel by adding .CSV to the file extension. Some output files are always generated, other files are optional. Box 1.4 provides an overview of the variables that are printed in each output file. All output files have the same header with the project name, file content, file name, model version, generation time, calculation period and soil profile depth. The output interval may range from 0.001 day to 1.0 year. If the output time only consists of a date, the output represents the situation at the end of the particular day. We may distinguish output of state variables, incremental fluxes since the last output time, and cumulative fluxes since a specified date. The output file with final values of state variables (OUTFIL.END) can be used as input for a subsequent simulation period. This might be useful to derive suitable initial conditions.

In addition to the ASCII files, formatted and unformatted (binary) export files can be generated with data that cover the entire simulation period. These output files can be used as input for advanced solute transport models, such as PEARL (Leistra et al., 2001) for pesticides and ANIMO (Groenendijk et al., 2005) for nutrients. A description of these export files is given in Appendix 14 and 15.

## 1.6 Case studies

Chapter 12 contains 6 case studies with SWAP. The input files of these cases come with the installation of SWAP. The case studies are:

- Hupsel Brook
- Grass growth
- Macropore flow
- Oxygen stress
- Salinity stress
- Surface water

The first case of a field in Hupsel Brook catchment includes a simulation with 3 different crop growth modules. This case is used to illustrate the input files in this SWAP manual.

## 1.7 Reading guide

In the next chapters we discuss subsequently:

- Chapter 2. Soil water flow
- Chapter 3. Evapotranspiration and rainfall interception
- Chapter 4. Surface runoff, interflow and drainage
- Chapter 5. Surface water system
- Chapter 6. Macropore flow
- Chapter 7. Crop growth
- Chapter 8. Solute transport
- Chapter 9. Soil heat flow
- Chapter 10. Snow and frost
- Chapter 11. Irrigation
- Chapter 12. Case studies

The first part of chapters 2-11 describe the physical relations incorporated in SWAP. This part also describes implemented numerical procedures, if required to use SWAP in a proper way. The second part of each chapter describes the model input. If relevant, suggestions for input are included.

The appendices contain information on:

- Application of the Penman Monteith method
- Derivation and examples of macropore equations
- Equations for the partial derivatives of  $F_i$  to pressure heads

- 
- Equations for the implicit linearization of hydraulic conductivities
  - Equations for the numerical solution of heat flow
  - Tables with soil hydraulic functions: Staring Series
  - Tables with critical pressure heads for root water extraction
  - Tables with salt tolerance data
  - Tables with shrinkage characteristic data
  - Tables with shrinkage characteristic data for peat soils
  - List of subroutines
  - List of fixed ranges of array lengths
  - Listing of formatted and unformatted binary output files
  - Acronyms in the WOFOST growth routine for grassland
  - Numerical scheme of soil water boundary conditions

---

## 2 Soil water flow

### 2.1 Basic equations

Gradients of the soil water potential cause soil water movement. Darcy's equation is commonly used to quantify this soil water movement. For one-dimensional vertical flow, Darcy's equation can be written as:

$$q = -K(h) \frac{\partial(h+z)}{\partial z} \quad (2.1)$$

where  $q$  is soil water flux density (positive upward) ( $\text{cm}^3 \text{cm}^{-2} \text{d}^{-1} = \text{cm d}^{-1}$ ),  $K(h)$  is hydraulic conductivity ( $\text{cm d}^{-1}$ ),  $h$  is soil water pressure head (cm) and  $z$  is the vertical coordinate (cm), taken positively upward.

Water balance considerations of an infinitely small soil volume result in the continuity equation for soil water:

$$\frac{\partial \theta}{\partial t} = -\frac{\partial q}{\partial z} - S_a(h) - S_d(h) - S_m(h) \quad (2.2)$$

where  $\theta$  is volumetric water content ( $\text{cm}^3 \text{cm}^{-3}$ ),  $t$  is time (d),  $S_a(h)$  is soil water extraction rate by plant roots ( $\text{cm}^3 \text{cm}^{-3} \text{d}^{-1}$ ),  $S_d(h)$  is the extraction rate by drain discharge in the saturated zone ( $\text{cm}^3 \text{cm}^{-3} \text{d}^{-1}$ ) and  $S_m(h)$  is the exchange rate with macro pores ( $\text{cm}^3 \text{cm}^{-3} \text{d}^{-1}$ ).

Combination of Eqs. (2.1) and (2.2) provides the general water flow equation in variably saturated soils, known as the Richards equation:

$$\frac{\partial \theta}{\partial t} = \frac{\partial \left[ K(h) \left( \frac{\partial h}{\partial z} + 1 \right) \right]}{\partial z} - S_a(h) - S_d(h) - S_m(h) \quad (2.3)$$

SWAP applies Richards equation integrally for the unsaturated-saturated zone, including possible transient and perched groundwater levels. SWAP solves Eq. (2.3) numerically, using specified boundary conditions and relations between  $\theta$ ,  $h$  and  $K$ .

### 2.2 Soil hydraulic functions

#### 2.2.1 General

SWAP uses the Mualem-Van Genuchten functions (Mualem, 1976; Van Genuchten, 1980) which have been used in numerous studies and form the base of several national and international data-bases (e.g. Carsel and Parrish, 1988; Yates et al., 1992; Leij et al., 1996; Wösten et al., 2001; Vereecken et al., 2010). The analytical  $\theta(h)$  function proposed by Van Genuchten (1980) reads:

$$\theta = \theta_{\text{res}} + (\theta_{\text{sat}} - \theta_{\text{res}}) \left( 1 + |\alpha h|^n \right)^{-m} \quad (2.4)$$

where  $\theta_{\text{sat}}$  is the saturated water content ( $\text{cm}^3 \text{cm}^{-3}$ ),  $\theta_{\text{res}}$  is the residual water content in the very dry range ( $\text{cm}^3 \text{cm}^{-3}$ ) and  $\alpha$  ( $\text{cm}^{-1}$ ),  $n$  (-) and  $m$  (-) are empirical shape factors. Without losing much flexibility,  $m$  can be taken equal to:

$$m = 1 - \frac{1}{n} \quad (2.5)$$

Using the above  $\theta(h)$  relation, with  $m = 1-1/n$ , and applying the theory on unsaturated hydraulic conductivity by Mualem (1976), the following  $K(\theta)$  function results:

$$K = K_{\text{sat}} S_e^\lambda \left[ 1 - \left( 1 - S_e^m \right)^m \right]^2 \quad (2.6)$$

where  $K_{\text{sat}}$  is the saturated conductivity (cm d<sup>-1</sup>),  $\lambda$  is a shape parameter (-) depending on flow path tortuosity, and  $S_e$  is the relative degree of saturation defined as:

$$S_e = \frac{\theta - \theta_{\text{res}}}{\theta_{\text{sat}} - \theta_{\text{res}}} \quad (2.7)$$

The numerical solution to the Richards equation requires an expression of the differential water capacity  $C$  (cm<sup>-1</sup>), which is defined as the derivative of  $\theta$  to  $h$  (Eq. (2.4):

$$C = \frac{\partial \theta}{\partial h} = \alpha m n |\alpha h|^{n-1} (\theta_{\text{sat}} - \theta_{\text{res}}) \left( 1 + |\alpha h|^n \right)^{-(m+1)} \quad (2.8)$$

A numerical approach to Eq. (2.3) yielding a steady-state solution requires an implicit treatment of the hydraulic conductivity. This implies the use of the derivative of the hydraulic conductivity to the pressure head  $dK/dh$ . Expressions are given in Appendix 5.

## 2.2.2 Modification near saturation

Near saturation a modification to the Mualem-Van Genuchten function (Schaap and Van Genuchten, 2006) has been implemented in SWAP. The modification is based on the introduction of a small minimum capillary height  $h_e$  which can be regarded as an air-entry value, causing a minor shift in the retention curve (Vogel et al., 2001). We follow Ippisch et al. (2006) by defining the relative water content as:

$$S_e = \begin{cases} \frac{1}{S_c} \left[ 1 + |\alpha h|^n \right]^{-m} & h < h_e \\ 1 & h \geq h_e \end{cases} \quad (2.9)$$

where  $S_e$  is the relative saturation at the cut-off point  $h_e$  in the original Van Genuchten model, given by:

$$S_c = \left[ 1 + |\alpha h_e|^n \right]^{-m} \quad (2.10)$$

The hydraulic conductivity is then given by:

$$K = \begin{cases} K_{\text{sat}} (S_e)^\lambda \left[ \frac{1 - (1 - (S_e S_c)^{1/m})^m}{1 - (1 - (S_c)^{1/m})^m} \right]^2 & S_e < 1 \\ K_{\text{sat}} & S_e \geq 1 \end{cases} \quad (2.11)$$

This model reduces to Eqs. [2.4] and [2.6] for  $h_e = 0$ . For a detailed discussion of above equations we refer to Vogel et al. (2001), Schaap and Van Genuchten (2006) and Ippisch et al. (2006). They showed that this modification affects the shape of the retention curve only minimally relative to the original function. However, the impacts on the unsaturated hydraulic conductivity of fine-textured soils can be large.

To avoid numerical instabilities of the solution scheme, the soil moisture retention curve in the range - 0.01 >  $h$  > 1.05  $h_e$  cm is approached by a cubic spline of which the parameters preserve the continuity of the soil moisture retention curve and the differential moisture capacity function.

A second modification concerns the saturated hydraulic conductivity itself. The parameter  $K_{sat}$  of the  $K(S_e)$  relation is usually derived from experiments with unsaturated flow. These experiments may yield a poor estimate of the hydraulic conductivity at saturated conditions where soil structure usually dominates soil texture. However, to simulate accurately runoff conditions and drainage, a correct value of the saturated hydraulic conductivity is essential. Therefore SWAP users may specify in addition to the parameter  $K_{sat}$  the experimentally determined value of the saturated hydraulic conductivity  $K_{sat,exp}$ . Close to saturation, in the range  $0 > h > -2$  cm, SWAP will linearly interpolate between  $K_{sat,exp}$  and  $K(S_e)$  at  $h = -2$  cm.

### 2.2.3 Soil hydraulic functions as tables

The (modified) uni-modal Mualem – van Genuchten representation of the  $\theta(h)$  and  $K(\theta)$  or  $K(h)$  relationships is just one of the many alternatives that are available in literature. Leij et al. (1997) listed 14 such relationships commonly used in soil physics, Leong and Rahardjo (1997) presented eight relationships often used in geotechnical science, and Kosugi et al. (2002) described the most widely used expressions, including those of Brooks and Corey (1964, 1966) and van Genuchten (1980). Currently in SWAP it has been decided not to implement many alternatives in the source code. Instead, the user is given the possibility to supply  $\theta(h)$  and  $K(h)$  relationships as tabulated input. In that way any relationship can be considered. During the computations interpolation is used to obtain  $\theta$ ,  $K$ ,  $C$  ( $= d\theta/dh$ ) and  $dK/dh$  for any  $h$ . Interpolation is done as piecewise cubic Hermite interpolation, preserving the monotonic character of the relationships (using PCHIP routines from the public domain software library SLATEC, <http://www.netlib.org/slatec/>). Due to the interpolation method, the outcome does depend on the user-supplied information in the input tables. Best results are obtained when the  $h$ - $\theta$ - $K$  tables contain many data points nicely distributed over all variables, with special attention to data close to saturation and data close to wilting point and beyond. For example, in case the user has data available measured in the laboratory it is advised to first describe these data by some kind of analytical expression, and then derive tables based on this analytical expression. Experience has shown that supplying a coarse (or irregular) grid of  $h$ - $\theta$ - $K$  data points may cause unrealistic behaviour of the interpolated results, e.g. in the derivation of  $C$ .

### 2.2.4 Hysteresis

Hysteresis refers to non-uniqueness of the  $\theta(h)$  relation and is caused by variations of the pore diameter (inkbottle effect), differences in radii of advancing and receding meniscus, entrapped air, thermal gradients and swelling/shrinking processes (Hillel, 1980; Feddes et al., 1988). Gradual desorption of an initially saturated soil sample gives the main drying curve, while slow absorption of an initially dry sample results in the main wetting curve. In the field partly wetting and drying occurs in numerous cycles, resulting in so-called drying and wetting scanning curves lying between the main drying and the main wetting curves (Figure 2.1).

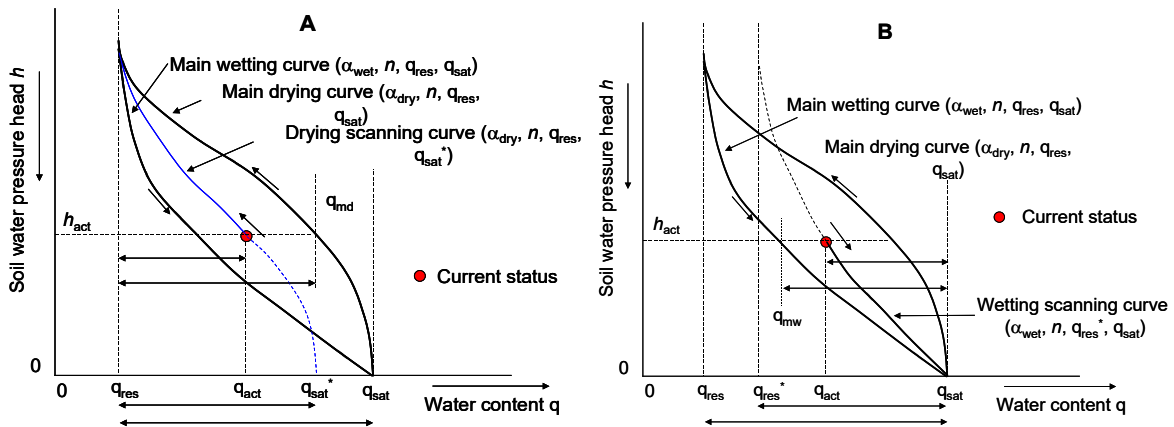

**Figure 2.1** Water retention function with hysteresis, showing the main wetting, main drying and scanning curves.

In simulation practice, often only the main drying curve is used to describe the  $\theta(h)$  relation. This is mainly due to the time and costs involved in measurement of the complete  $\theta(h)$  relationship, including the main wetting, the main drying and the scanning curves, especially in the dry range. For instance, a generally applied soil hydraulic data base in The Netherlands, known as the Staring series (Wösten et al., 1994, 2001), contains only  $\theta(h)$  data of the main drying curve. Nevertheless, it is obvious that the simulation of infiltration events with the main drying curve can be inaccurate. Therefore the scaling method of Scott et al. (1983), who derived scanning curves by rescaling the main wetting or the main drying curve to the actual water content, has been implemented in SWAP.

The main drying and main wetting curve are described analytically with the Mualem-van Genuchten parameters ( $\alpha$ ,  $n$ ,  $\theta_{res}$ ,  $\theta_{sat}$ ,  $K_{sat}$ , and  $\lambda$ ). Some of the parameters describing the main wetting and main drying curve are related. We assume  $\theta_{res}$  and  $\theta_{sat}$  to be equal for both curves. Usually the  $K(\theta)$  function shows only minor hysteresis effects, which can be achieved by choosing for the main wetting and main drying curve a common value for  $n$ . Ultimately the two curves only differ in the parameter  $\alpha$ , as depicted in Figure 2.2. The scanning curves are derived by linear scaling of either the main wetting or main drying curve, such that the scanning curve includes the current  $\theta$ - $h$  combination and approaches the main wetting curve in case of a wetting scanning curve and the main drying curve in case of a drying scanning curve.

The scaling principle in case of a drying scanning curve is depicted in Figure 2.2A. Based on its wetting and drying history, at a certain time and depth the soil shows an actual water content  $\theta_{act}$  at the soil water pressure head  $h_{act}$ . The valid drying scanning curve should pass through the point  $(\theta_{act}, h_{act})$ , and approach the main drying curve at smaller water contents.

**Figure 2.2** (A) Linear scaling of the main drying water retention curve in order to derive a drying scanning curve; (B) Linear scaling of the main wetting water retention curve in order to derive a drying wetting curve.

We may define  $\theta_{md}$  as the water content of the main drying curve at  $h_{act}$ , and  $\theta_{sat}^*$  as the saturated water content of the drying scanning curve. Linear scaling of the main drying curve with respect to the vertical axis  $\theta = \theta_{res}$  gives (Figure 2.2A):

$$\frac{\theta_{sat}^* - \theta_{res}}{\theta_{sat} - \theta_{res}} = \frac{\theta_{act} - \theta_{res}}{\theta_{md} - \theta_{res}} \Rightarrow \theta_{sat}^* = \theta_{res} + (\theta_{sat} - \theta_{res}) \frac{\theta_{act} - \theta_{res}}{\theta_{md} - \theta_{res}} \quad (2.12)$$

The only unknown in Eq. (2.12) is  $\theta_{sat}^*$ , which can be solved directly. The drying scanning curve is described accordingly with the parameters  $(\alpha_{dry}, n, \theta_{res}, \theta_{sat}^*)$ . As long as the soil keeps drying, this drying scanning curve is valid.

The opposite occurs when the soil gets wetter. Again we start from the arbitrary actual water content  $\theta_{act}$  at the soil water pressure head  $h_{act}$ , and now define  $\theta_{mw}$  as the water content of the main wetting

curve at  $h_{act}$ , and  $\theta_{res}^*$  as the residual water content of the wetting scanning curve. Linear scaling of the main wetting curve with respect to the vertical axis  $\theta = \theta_{sat}$  gives (Figure 2.2B):

$$\frac{\theta_{sat} - \theta_{res}^*}{\theta_{sat} - \theta_{res}} = \frac{\theta_{sat} - \theta_{act}}{\theta_{sat} - \theta_{mw}} \Rightarrow \theta_{res}^* = \theta_{sat} - (\theta_{sat} - \theta_{res}) \frac{\theta_{sat} - \theta_{act}}{\theta_{sat} - \theta_{mw}} \quad (2.13)$$

From Eq. (2.13),  $\theta_{res}^*$  can be directly solved. The wetting scanning curve is accordingly described with the parameters  $(\alpha_{wet}, n, \theta_{res}^*, \theta_{sat})$ , and is valid as long as the soil keeps wetting. As the wetting-drying history is different at each soil depth, each node may show a different scanning curve. The unique  $K(\theta)$  relation of a soil layer always follows from the parameter set  $(n, \theta_{res}, \theta_{sat}, K_{sat}, \lambda)$  according to Eq. (2.6).

## 2.2.5 Frozen soil conditions

The effect of frozen soil moisture on the hydraulic conductivity is described by:

$$K^* = K_{min} + (K - K_{min}) \cdot \max(0, \min(1, \frac{T - T_2}{T_1 - T_2})) \quad (2.14)$$

where  $K^*$  is the adjusted hydraulic conductivity ( $\text{cm d}^{-1}$ ),  $T$  is the soil temperature ( $^{\circ}\text{C}$ ),  $T_1$  and  $T_2$  ( $^{\circ}\text{C}$ ) denote the temperature range over which the hydraulic conductivity linearly declines, and  $K_{min}$  is a minimum value of the hydraulic conductivity ( $\text{cm d}^{-1}$ ) which is valid for temperatures less than  $T_2$ .

## 2.3 Lower boundary condition

The bottom boundary of the one-dimensional SWAP is either in the unsaturated zone or in the upper part of the saturated zone where the transition takes place to three-dimensional groundwater flow. The lower boundary conditions in SWAP can be specified, depending on the application and the relevant spatial scale.

Three general types and some special cases of lower boundary conditions are distinguished:

### 1. The Dirichlet condition

The head controlled boundary is often referred as to the Dirichlet condition and involves the imposing of a pressure head  $h_{bot}$  at the lower boundary. A special case involves the use of a recorded groundwater elevation. The pressure head at the groundwater elevation  $\phi_{avg}$  is defined as  $h = 0$ . This yields a linear relation between the pressure heads at the grid points above and below  $\phi_{avg}$ :

$$h_{i+1} = -h_i \frac{\phi_{avg} - z_{i+1}}{z_i - \phi_{avg}} \quad (2.15)$$

### 2. The Neumann condition

The flux boundary condition is often referred as to the Neumann condition and involves prescribing a flux  $q_{bot}$  at the bottom. Since the model employs an explicit linearization scheme, the flux - groundwater level relations are treated as a Neumann condition, where the actual flux is calculated from the groundwater level of the previous time step. The relation between flux and groundwater level can be obtained from regional groundwater flow models (e.g. Van Bakel, 1986). Some special options are available to define  $q_{bot}$ :

- A zero bottom flux may be applied when an impermeable layer exists at the bottom of the profile.
- Impose a time series of  $q_{bot}$
- Calculate  $q_{bot}$  at the start of a time step as a function of the groundwater level  $\phi_{avg}$  of the previous timestep, either by interpolation in a tabulated function or by using an exponential function, defined as:

$$q_{bot} = a_{bot} \exp(b_{bot} |\phi_{avg}|) + c_{bot} \quad (2.16)$$

where  $a_{bot}$  ( $\text{cm d}^{-1}$ ),  $b_{bot}$  ( $\text{cm}^{-1}$ ) and  $c_{bot}$  ( $\text{cm d}^{-1}$ ) are empirical coefficients.

- Calculate  $q_{\text{bot}}$  at the start of a time step as a function of the groundwater level  $\phi_{\text{avg}}$  of the previous timestep, the hydraulic head in a semi-confined aquifer  $\phi_{\text{aquif}}$  (cm), and the resistance of the semi-confining layer  $c_1$  (d), according to:

$$q_{\text{bot}} = \frac{\phi_{\text{aquif}} - \phi_{\text{avg}}}{c_1 + \sum_{i=i_{\text{gwl}}}^n \frac{\Delta z_i}{K_{\text{sat},i}}} \quad (2.17)$$

where the subscript  $i_{\text{gwl}}$  points to the compartment number in which the groundwater level is located. The flow resistance in the saturated zone between the groundwater level and the lower boundary has been accounted for by summation of the flow resistances  $\frac{\Delta z_i}{K_{\text{sat},i}}$  in this zone. Different options for defining  $\phi_{\text{aquif}}$  are available.

### 3. The Cauchy condition

In this case the flux  $q$  at the lower boundary is defined as a function of the prevailing pressure head. This condition can be used when unsaturated flow models are combined with models for regional groundwater flow and when an implicit handling of  $q_{\text{bot}}$  in the iterative computation scheme is required. The flux through the bottom boundary is defined by the difference of the total hydraulic head ( $h+z$ ) and the hydraulic head  $\phi$  (cm) of the regional groundwater outside the flow domain described by the model, divided by a flow resistance  $c$  (d).

$$q_{\text{bot}} = \frac{[h+z]_{z=\text{bot}} - \phi}{c} \quad (2.18)$$

### 4. Special cases

Two special cases involve the option to define a seepage face at the lower boundary and to define free drainage. The seepage face is meant to simulate moisture flow in a lysimeter and combines a head controlled and zero flux controlled condition in the following way:

$$\begin{aligned} h_{z=\text{bot}} < 0 &\rightarrow q_{\text{bot}} = 0 \\ h_{z=\text{bot}} \geq 0 &\rightarrow q_{\text{bot}} = -K_n \left[ \frac{\partial(h+z)}{\partial z} \right]_{z=\text{bot}} \quad \text{setting } h_{z=\text{bot}} = 0 \end{aligned} \quad (2.19)$$

The free drainage option results from the assumption that the pressure head gradient equals zero, implying that  $q_{\text{bot}}$  equals the hydraulic conductivity of the lowest compartment  $n$ :

$$\left[ \frac{\partial(h+z)}{\partial z} \right]_{z=\text{bot}} = 1 \rightarrow q_{\text{bot}} = -K_n \quad (2.20)$$

During frost conditions,  $q_{\text{bot}}$  will be reduced according to:

$$q_{\text{bot}} = f_T(z) q_{\text{bot}} \quad (2.21)$$

where the reduction factor  $f_T$  is based on Eq. (2.14). The bottom flux can be reduced even further in case of the presence of frozen layers (see Chapter 10).

## 2.4 Numerical implementation

Accurate numerical solution of the Richards partial differential equation is difficult due to its hyperbolic nature, the strong non-linearity of the soil hydraulic functions and the rapid changing boundary conditions near the soil surface. Calculated soil water fluxes can be significantly affected by the structure of the numerical scheme, the applied time and space discretizations, and the procedure for the top boundary condition (Van Genuchten, 1982; Milly, 1985; Celia et al., 1990; Warrick, 1991; Zaidel and Russo, 1992). The numerical scheme chosen in SWAP solves the one-dimensional Richards equation with an accurate mass balance and converges rapidly. This scheme in combination with the top boundary procedure has been shown to handle rapid soil water movement during infiltration in dry soils accurately. At the same time the scheme is computationally efficient (Van Dam and Feddes, 2000).

## 2.4.1 Richards equation

The current numerical scheme of SWAP to solve Richards equation is the implicit, backward, finite difference scheme with explicit linearization of hydraulic conductivities as described by Haverkamp et al. (1977) and Belmans et al. (1983), but with the following adaptations:

- The numerical scheme applies to both the unsaturated and saturated zone and the flow equations are solved in both zones simultaneously;
- The water storage term  $\frac{\partial \theta}{\partial t}$  is evaluated instead of using an approximation for the term  $C \frac{\partial h}{\partial t}$ , where  $C$  is the water capacity ( $\text{cm}^{-1}$ );
- There are several options for calculating the internodal conductivity.

The implicit, backward, finite difference scheme of Eq. (2.3) with explicit linearization, yields the following discretization of Richards equation:

$$\frac{\theta_i^{j+1} - \theta_i^j}{\Delta t^j} = \frac{1}{\Delta z_i} \left[ K_{i-1/2}^{j+\kappa} \frac{h_{i-1}^{j+1} - h_i^{j+1}}{1/2(\Delta z_{i-1} + \Delta z_i)} + K_{i-1/2}^{j+\kappa} - K_{i+1/2}^{j+\kappa} \frac{h_i^{j+1} - h_{i+1}^{j+1}}{1/2(\Delta z_i + \Delta z_{i+1})} - K_{i+1/2}^{j+\kappa} \right] - S_{a,i}^j - S_{d,i}^j - S_{m,i}^{j+1} \quad (2.22)$$

where  $\Delta t^j = t^{j+1} - t^j$  and  $\Delta z_i$  is the compartment thickness. Handling of the water storage term is further elaborated in the next section. The sink terms representing the root extraction  $S_a$  and the flow to drains  $S_d$  are evaluated at the old time level  $j$  (explicit linearization). The macro pore exchange rate  $S_m$  is evaluated at the new time level  $j+1$  and the internodal conductivity  $K_{i-1/2}^{j+\kappa}$  can be evaluated at the old time level  $j$  ( $\kappa = 0$ ) or at the new time level  $j+1$  ( $\kappa = 1$ ). The internodal conductivity  $K_{i-1/2}^{j+\kappa}$  can be calculated as:

$$\text{Arithmetic mean:} \quad K_{i-1/2}^{j+\kappa} = 1/2 \left( K_{i-1}^{j+\kappa} + K_i^{j+\kappa} \right) \quad (2.23)$$

$$\text{Weighted arithmetic mean:} \quad K_{i-1/2}^{j+\kappa} = \frac{\Delta z_{i-1} K_{i-1}^{j+\kappa} + \Delta z_i K_i^{j+\kappa}}{\Delta z_{i-1} + \Delta z_i} \quad (2.24)$$

$$\text{Geometric mean:} \quad K_{i-1/2}^{j+\kappa} = \left( K_{i-1}^{j+\kappa} \right)^{1/2} \left( K_i^{j+\kappa} \right)^{1/2} \quad (2.25)$$

$$\text{Weighted geometric mean:} \quad K_{i-1/2}^{j+\kappa} = \left( K_{i-1}^{j+\kappa} \right)^{\frac{\Delta z_{i-1}}{\Delta z_{i-1} + \Delta z_i}} \left( K_i^{j+\kappa} \right)^{\frac{\Delta z_i}{\Delta z_{i-1} + \Delta z_i}} \quad (2.26)$$

Haverkamp and Vauclin (1979), Belmans et al. (1983) and Hornung and Messing (1983) proposed to use the geometric mean. In their simulations the geometric mean increased the accuracy of calculated fluxes and caused the fluxes to be less sensitive to changes in nodal distance. However, the geometric mean has serious disadvantages too (Warrick, 1991). When simulating infiltration in dry soils or high evaporation from wet soils, the geometric mean severely underestimates the water fluxes. Other researchers proposed to use the harmonic mean of  $K$  or various kind of weighted averages (Ross, 1990; Warrick, 1991; Zaidel and Russo, 1992; Desbarats, 1995). Van Dam and Feddes (2000) showed that, although arithmetic averages at larger nodal distances overestimate the soil water fluxes in case of infiltration and evaporation events, at nodal distances in the order of 1 cm non-weighted arithmetic averages are more close to the theoretically correct solution than geometric averages. Also they show that the remaining inaccuracy between calculated and theoretically correct fluxes, is relatively small compared to expected effects of soil spatial variability and hysteresis. Therefore the SWAP development team has a preference for applying weighted arithmetic averages of  $K$ , which is in line with commonly applied finite element models (Kool and Van Genuchten, 1991; Šimůnek et al., 1992). Therefore default choices are weighted arithmetic mean and no update of hydraulic conductivity.

Starting in the saturated zone, the groundwater table is simply found at  $h = 0$ . Also perched water tables may occur above dense layers in the soil profile. Since SWAP is designed to describe a wide range of layered soil profiles combined with different types of boundary conditions, the nodal distance is made variable and should be specified by the user.

## 2.4.2 Numerical solution

The discrete form of the Richards equation is solved iteratively using the pressure heads as state variables. Taylor-expansion of the new moisture fraction at a new iteration level with respect to the moisture fraction at the preceding iteration step is defined by:

$$\theta_i^{j+1,p+1}(h_i^{j+1}) \approx \theta_i^{j+1,p}(h_i^{j+1,p}) + (h_i^{j+1,p+1} - h_i^{j+1,p}) \frac{\partial \theta_i^{j+1,p}}{\partial h_i^{j+1,p}} + \dots + \dots \quad (2.27)$$

Ignoring the second and higher order terms of the Taylor series yields an expression which can substitute the moisture fraction variable at the new time-level. The first order derivate of the moisture fraction to the pressure head is identical to the water capacity  $C^{j+1,p}$ . In fact the numerical method proposed by Celia et al. (1990) complies with the assumptions made in the Newton-Raphson iteration procedure. An improvement to this method is made by defining  $F_i$  based on the closure term of the water balance as a function of  $h_i^{j+1}$ :

$$F_i = \frac{\Delta z_i}{\Delta t^j} (\theta_i^{j+1,p} - \theta_i^j) - K_{i-\frac{1}{2}}^{j+\kappa,\kappa p} \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} - K_{i-\frac{1}{2}}^{j+\kappa,\kappa p} + K_{i+\frac{1}{2}}^{j+\kappa,\kappa p} \frac{h_i^{j+1,p} - h_{i+1}^{j+1,p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + K_{i+\frac{1}{2}}^{j+\kappa,\kappa p} + \Delta z_i S_{a,i}^{j+\kappa,p} + \Delta z_i S_{d,i}^j + \Delta z_i S_{m,i}^{j+1,p} \quad (2.28)$$

where the superscript  $p+1$  points to the solution of iteration round  $p$ . This discrete form of the Richards equation allows for a straightforward evaluation of the storage term and is flexible with the respect to adding of  $h_i^{j+1}$ -dependent source and sink-terms. Solving the set of non-linear equations numerically implies root finding of the function  $F_i \approx 0$  for  $i=1..n$ , with  $n$  the number of compartments. The Newton Raphson-iteration scheme for the set of  $n$  equations is written as follows:

$$\begin{pmatrix} h_1^{j+1,p+1} \\ \vdots \\ h_i^{j+1,p+1} \\ \vdots \\ h_n^{j+1,p+1} \end{pmatrix} = \begin{pmatrix} h_1^{j+1,p} \\ \vdots \\ h_i^{j+1,p} \\ \vdots \\ h_n^{j+1,p} \end{pmatrix} - \begin{pmatrix} \frac{\partial F_1}{\partial h_1^{j+1,p}} & \frac{\partial F_1}{\partial h_2^{j+1,p}} & 0 & 0 & 0 \\ \frac{\partial F_2}{\partial h_1^{j+1,p}} & \frac{\partial F_2}{\partial h_2^{j+1,p}} & \dots & 0 & 0 \\ 0 & \frac{\partial F_i}{\partial h_{i-1}^{j+1,p}} & \frac{\partial F_i}{\partial h_i^{j+1,p}} & \frac{\partial F_i}{\partial h_{i+1}^{j+1,p}} & 0 \\ 0 & 0 & \dots & \frac{\partial F_{n-1}}{\partial h_{n-1}^{j+1,p}} & \frac{\partial F_{n-1}}{\partial h_n^{j+1,p}} \\ 0 & 0 & 0 & \frac{\partial F_n}{\partial h_{n-1}^{j+1,p}} & \frac{\partial F_n}{\partial h_n^{j+1,p}} \end{pmatrix}^{-1} \begin{pmatrix} F_1 \\ \vdots \\ F_i \\ \vdots \\ F_n \end{pmatrix} \quad (2.29)$$

The starting values are the results of the previous iteration round, indicated by the superscript  $p$ . The solution of the second part of the right hand side is found by solving efficiently a tri-diagonal system of equations (Press et al., 1989). The coefficients of the Jacobian are listed in Appendix 4. The

contribution of the partial derivative of the macro-pore exchange to the pressure head ( $\frac{\partial S_{m,i}^{j+1,p}}{\partial h_i^{j+1,p}}$ ) is

discussed in Chapter 6. If the option to treat the hydraulic conductivities implicitly is used ( $\kappa=1$ ), the contribution of the partial derivatives of the internodal conductivity relation to the pressure head should also accounted. Expressions for these terms are given in Appendix 5.

Newton's method for solving nonlinear equations might wander off into the wild blue yonder if the initial guess is not sufficiently close to the root.

**Figure 2.3** Influence of initial estimate on an intermediate solution of a first order approximation based root finding procedure.

The solution to the second part of the right hand side of Eq. (2.29) is referred to as the Newton-step  $\Delta h_i^{j+1,p}$  :

$$\begin{pmatrix} h_1^{j+1,p+1} \\ \vdots \\ h_i^{j+1,p+1} \\ \vdots \\ h_n^{j+1,p+1} \end{pmatrix} = \begin{pmatrix} h_1^{j+1,p} \\ \vdots \\ h_i^{j+1,p} \\ \vdots \\ h_n^{j+1,p} \end{pmatrix} + \lambda \begin{pmatrix} \Delta h_1^{j+1,p} \\ \vdots \\ \Delta h_i^{j+1,p} \\ \vdots \\ \Delta h_n^{j+1,p} \end{pmatrix} \quad (2.30)$$

We always first try the full Newton step and we check at each iteration that the proposed step reduces  $\frac{1}{2} \sum_{i=1}^n F_i^2$ . If not, we backtrack along the Newton direction until we have an acceptable step. The aim is to find  $\lambda$  which results in a decrease of

$$\frac{1}{2} \sum_{i=1}^n [F_i(h_i^{j+1,p} + \lambda \Delta h_i^{j+1,p})]^2.$$

The first estimate of  $\lambda$  amounts to 1. If it is decided that a second estimate is needed,  $\lambda$  is set to 1/3. The third estimate amounts to 1/9. Thereafter, no further reduction of  $\lambda$  is applied but a new Newton-iteration step is performed.

In SWAP the main convergence criterium in the unsaturated zone is based on the water closure term of the water balance  $F$ . If  $|F_i|$  is less than a user defined criterion for all compartments, it is decided that the iteration cycle has resulted into a sufficiently accurate solution.

Numerical implementation of the top and bottom boundary conditions is described in Appendix 17.

---

## 2.5 User instructions

### 2.5.1 General

Box 2.1 shows the general input of soil water flow. The initial soil moisture condition (**Part 1**) is defined by the soil water pressure head. Initial values can be specified as function of soil depth with linear interpolation between depths or can be calculated assuming hydrostatic equilibrium with a groundwater level. A third option is to use the output of an earlier SWAP simulation. This option is very useful when no data are available of the initial soil moisture condition.

**Part 4** describes the vertical discretization of the soil profile. In addition to the natural soil layers with different hydraulic functions, the thicknesses of the calculation compartments should be defined. For correct simulation of infiltration and evaporation fluxes near the soil surface, the compartment thickness near the soil surface should be  $\leq 1$  cm. Deeper in the soil profile, where the soil water flow is less dynamic, the compartment thicknesses may increase (to 10 or more cm). In **Part 5** the hydraulic parameters of each distinct soil layer are defined, which describe the water retention and hydraulic conductivity functions. The use of the air-entry-value concept  $h_e$  requires special care. Even a small value of  $|h_e|$  can cause a large change in  $K(\theta)$  of fine-textured soils (see Section 2.2.2). In fact, the use of the air-entry-value concept requires the re-fitting of the other parameters of the classical Mualem-Van Genuchten model on the original experimental data. In case the soil hydraulic functions are provided as tables, for each soil layer a separate file should be provided. Each file should provide the following column-oriented data: headtab (for  $h$ ), thetab (for  $\theta$ ) and conductab (for  $K$ ). Due to the interpolation method, the outcome does depend on the user-supplied information in the input tables. Best results are obtained when the  $h$ - $\theta$ - $K$  tables contain many data points nicely distributed over all variables (e.g., based on equal log-transformed  $h$  interval (e.g., 0.1), or a dense grid of effective degree of saturation), with special attention to data close to saturation and data close to wilting point and beyond (see example in Table 2.2). For example, in case the user has data available measured in the laboratory it is advised to first describe these data by some kind of analytical expression, and then derive tables based on this analytical expression. Experience has shown that supplying a coarse (or irregular) grid of  $h$ - $\theta$ - $K$  data points may cause unrealistic behaviour of the interpolated results, e.g. in the derivation of  $C$ .

The piecewise cubic Hermite interpolation requires information regarding the behaviour at the end-points of the tabulated data. Currently, this is internally defined as provided in Table 2.1. The current pre-defined behaviour at the end-points is in agreement with the analytical behaviour of the Mualem-van Genuchten relationships. In case other relationships are used, this behaviour might be in conflict with these pre-defined characteristics. In a future release this might be solved by giving the user the opportunity to supply endpoint behaviour as input.

**Table 2.1** Currently the behaviour of the interpolation technique at the end-points of the tabulated water retention and tabulated hydraulic conductivity relationships are fixed according to the first or second derivatives as provided here.

End point in $h$	Retention	Conductivity	Comment
$h = 0$	$d\theta/dh = 0$	$d^2K/dh^2 = 0$	Data for $h = 0$ must be provided
$h \rightarrow -\infty$	$d^2\theta/dh^2 = 0$	$d^2K/dh^2 = 0$	Thus data for a very large negative value should be provided

**Table 2.2** Example of tabulated soil physical input data for a soil layer. In this case headtab, thetatab and conductab were constructed from the Mualem-van Genuchten relationship for effective degrees in saturation of  $S_e = 0.001, 0.01, 0.02, 0.03, \dots, 0.99, 0.991, 0.992, \dots, 0.999, 0.9991, 0.9992, \dots, 0.9999, 1$ .

In **Part 6** the inclusion of hysteresis in the water retention function can be selected. In case of hysteresis, the parameter ALFAW of the wetting curve (**Part 5**) should be properly defined. Whether the initial condition is wetting or drying, may have a large impact on the water balance. In general the simulations are not sensitive to the minimum head difference to change from wetting to drying scanning curves and vice versa (TAU). The parameter TAU is usually set equal to 0.2 cm.

In **Part 10** various parameters are defined that may affect the numerical solution of the Richards equation. In general, the default values will guarantee an accurate numerical solution of the Richards equation for common soil profiles. In extreme hydrologic or textural cases adjustment of the default values might be required. The user should specify a minimum and a maximum time step,  $\Delta t_{\min}$  and  $\Delta t_{\max}$  (d). SWAP will determine the optimal time step which minimizes the computational effort of a simulation while the numerical solution still meets the convergence criteria. For this purpose, SWAP employs the number of iterations needed to reach convergence,  $N_{it}$ , in the following way (Kool and Van Genuchten, 1991):

- $N_{it} < 3$  : multiply time step with a factor 2
- $3 \leq N_{it} \leq N_{\max}$  : keep time step the same
- $N_{it} > N_{\max}$  : divide time step by a factor 2

where  $N_{\max}$  is the defined maximum number of iterations (default 30). Also the maximum number of back-track cycles should be specified by the user. A common value for this maximum is 3.

Routinely, SWAP uses 4 convergence criteria:

- the water balance error of each soil compartment: should be less than  $10^{-6}$  cm
- between iterations the relative difference in pressure head (-) per compartment should be less than a user specified criterion (CritDevH1CP, e.g.  $10^{-2}$ )
- between iterations the absolute difference in pressure head (cm) per compartment should be less than a user specified criterion (CritDevH2CP, e.g.  $10^{-1}$  cm)
- the water balance error of a possible ponding layer should be less than a user specified criterion (CritDevPondDt, e.g.  $10^{-4}$  cm)

In addition, SWAP will give a warning when groundwater levels between time steps fluctuate more than a user specified criterion (GWLCONV).

For the initial time step, SWAP will take  $\Delta t = \sqrt{\Delta t_{\min} \Delta t_{\max}}$ . Depending on  $N_{it}$ , the time step will be decreased, maintained or increased for the following time steps as described above. The time step is always confined to the range  $\Delta t_{\min} \leq \Delta t \leq \Delta t_{\max}$ . When the actual time step during simulation reaches its minimum value ( $\Delta t = \Delta t_{\min}$ ), the maximum number of iterations is expanded to  $2 * N_{\max}$ . If still the numerical solution shows no convergence, SWAP prints a warning in the log file, and continues the simulation at the next time step with the pressure heads of the last iteration.

In Part 10 also a choice can be made with respect to spatial averaging of hydraulic conductivity and updating hydraulic conductivity in the numerical solution. Default choices are weighted arithmetic mean (SWKMEAN = 2) and no update of hydraulic conductivity (SWKIMPL = 0) (see also paragraph 2.4.1).

## 2.5.2 Bottom boundary conditions

SWAP offers various options to prescribe the lower boundary condition, each having their typical scale of application (Table 2.3, Box 2.2).

**Table 2.3** Options for the lower boundary condition.

Lower boundary condition	Description	Type of condition	Typical scale of application
1	Prescribe groundwater level	Dirichlet	field
2	Prescribe bottom flux ( $q_{bot}$ )	Neumann	region
3	Calculate bottom flux from hydraulic head of deep aquifer	Cauchy	region
4	Calculate bottom flux as function of groundwater level	Cauchy	region
5	Prescribe soil water pressure head of bottom compartment	Dirichlet	field
6	Bottom flux equals zero	Neumann	field / region
7	Free drainage of soil profile	Neumann	field
8	Free outflow at soil-air interface (seepage face)	Neumann / Dirichlet	field

In case of options 1, 2, 3, 5 and 6, in addition to the flux across the bottom of the modelled soil profile ( $q_{bot}$ ), a drainage flux ( $q_{drain}$ ) can be defined (Chapter 4). In case of option 4, the lower boundary includes drainage to local ditches or drains so  $q_{drain}$  should not be defined separately. In case of options 7 and 8, the simulated soil profile is unsaturated, so lateral drainage will not occur. We will discuss the 8 available bottom boundary conditions sequentially.

### 1. Prescribed groundwater levels

In this case a field-averaged groundwater level ( $\phi_{avg}$ ) is given as a function of time (Box 2.2). SWAP will linearly interpolate between the dates and times at which the groundwater levels are specified. SWAP will read times according to the following format: 05-jan-2005\_14:30:00.00 denotes January 5, 2005 at 2.30 PM. If only dates and no times are specified (as in Box 2.2), SWAP will assume time 0:00.

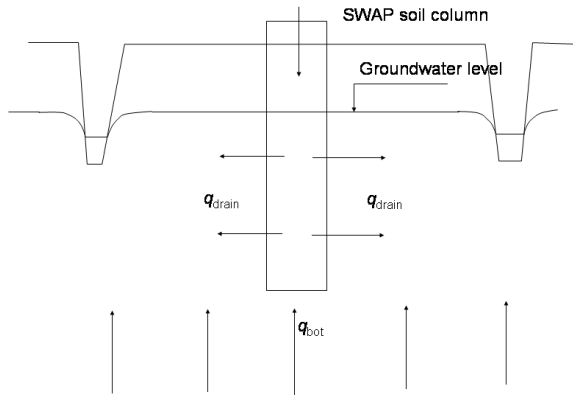

The main advantage of this boundary condition is the easy recording of the phreatic surface in case of a present groundwater table. A drawback is that at shallow groundwater tables the simulated phreatic surface fluctuations are very sensitive to the soil hydraulic functions and the top boundary condition. If the top and bottom boundary condition not match accurately, or the soil hydraulic functions deviate from reality, strong fluctuations of simulated water fluxes across the lower boundary may result. Especially when the output of SWAP is used as input in water quality calculations, it is recommended to use another type of lower boundary condition. The option of prescribed groundwater levels is disabled for macropore flow simulations.

Experience has shown that SWAP cannot correctly handle this boundary condition in case the (interpolated) prescribed groundwater level is inside frozen soil. An alternative boundary condition to achieve approximately the desired groundwater levels is to impose pressure heads at the bottom of the simulated soil profile which are in hydrostatic equilibrium with the desired phreatic surface (Option 5).

### 2. Prescribed bottom flux

In this case the bottom flux ( $q_{bot}$ ) might be given as function of time with linear interpolation between the data pairs, or as a sine function (Box 2.2). This option has a similar disadvantage as the previously described option with the prescribed groundwater level at the field scale. When a mismatch occurs between boundary conditions (e.g. drainage + leakage to deep aquifer exceeds net precipitation excess) the result may be a continuously declining or increasing groundwater level. In particular in cases where the output of SWAP is used as input in water quality calculations, it is recommended to use another type of lower boundary condition.

### 3. Calculate the bottom flux from the hydraulic head of a deep aquifer

**Figure 2.4** Pseudo two-dimensional Cauchy lower boundary conditions, in case of drainage to ditches and seepage from a deep aquifer.

Figure 2.4 shows a soil profile which is drained by ditches and which receives a seepage flux from a semi-confined aquifer. SWAP makes a distinction between  $q_{\text{drain}}$ , the local drainage flux to ditches and drains (see Chapter 4), and  $q_{\text{bot}}$ , the bottom flux due to regional groundwater flow.

The bottom flux  $q_{\text{bot}}$  depends on the average groundwater level  $\phi_{\text{avg}}$  (cm), the hydraulic head in the semi-confined aquifer  $\phi_{\text{aquif}}$  (cm), and the resistance of the semi-confining layer  $c_1$  (d):

$$q_{\text{bot}} = \frac{\phi_{\text{aquif}} - \phi_{\text{avg}}}{c_1 + \sum_{i=i_{\text{gwl}}}^n \frac{\Delta z_i}{K_{\text{sat},i}}} \quad (2.31)$$

where the subscript  $i_{\text{gwl}}$  points to the compartment number in which the groundwater level is located. The vertical resistance between the bottom of the model and the groundwater level may be taken into account by adding it to the aquitard resistance  $c_1$ . The hydraulic head  $\phi_{\text{aquif}}$  is prescribed using a sinusoidal wave:

$$\phi_{\text{aquif}} = \phi_{\text{aquif},m} + \phi_{\text{aquif},a} \cos\left(\frac{2\pi}{\phi_{\text{aquif},p}}(t - t_{\text{max}})\right) \quad (2.32)$$

where  $\phi_{\text{aquif},m}$ ,  $\phi_{\text{aquif},a}$ , and  $\phi_{\text{aquif},p}$  are the mean (cm), amplitude (cm) and period (d) of the hydraulic head sinus wave in the semi-confined aquifer, and  $t_{\text{max}}$  is the time (d) at which  $\phi_{\text{aquif}}$  reaches its maximum.

SWAP includes the option for the implicit treatment of pressure head in lowest compartment by substitution of  $\phi_{\text{avg}}$  by  $h_n^{j+1} + z_n$  and considering the vertical resistance within the model domain only between the lowest node and the lower boundary. Another option involves the possibility to specify a groundwater flux additional to  $q_{\text{bot}}$  to facilitate the coupling of the SWAP model to a regional groundwater model.

### 4. Calculate bottom flux as a function of groundwater level

The relation between  $q_{\text{bot}}$  and  $\phi_{\text{avg}}$  can be given as an exponential relation or as a table (Box 2.2). The exponential relationship is formulated as:

$$q_{\text{bot}} = a_{\text{qbot}} \exp\left(b_{\text{qbot}} |\phi_{\text{avg}}|\right) + c_{\text{qbot}} \quad (2.33)$$

where  $a_{\text{qbot}}$  ( $\text{cm d}^{-1}$ ),  $b_{\text{qbot}}$  ( $\text{cm}^{-1}$ ) and  $c_{\text{qbot}}$  ( $\text{cm d}^{-1}$ ) are empirical coefficients. This type of exponential relationship was derived for deep sandy areas in the eastern part of The Netherlands (Massop and De Wit, 1994).

Special care should be taken with respect to the distinction between drainage and bottom boundary flux. The relationship that may be used to compute drainage (Chapter 4) can conflict with the relation for  $q_{\text{bot}}$ . It may then be appropriate to apply another type of boundary condition.

When the relation between  $q_{\text{bot}}$  and  $\phi_{\text{avg}}$  is given as a table,  $q_{\text{bot}}$  results from an interpolation between groundwater level and bottom flux listed in the table, using the simulated groundwater level ( $\phi_{\text{gwl}}$ ).

### 5. Prescribed soil water pressure heads at the bottom of the model

In this case values of  $h_{\text{bot}}$  should be specified as function of time. For times between observations, SWAP will interpolate linearly.

## 6. Zero flux at the bottom of the model domain

A bottom flux ( $q_{\text{bot}}$ ) of zero may be applied when an impervious layer exists at the profile bottom or when groundwater flow below the profile bottom can be neglected. This option is implemented with a simple switch, which forces  $q_{\text{bot}}$  to zero.

## 7. Free drainage

In case of free drainage, the total hydraulic head  $H$  gradient is assumed to be equal to one at the bottom boundary, which sets  $q_{\text{bot}}$  equal to the hydraulic conductivity of the lowest compartment:

$$\frac{\partial H}{\partial z} = 1 \quad \text{thus: } q_{\text{bot}} = -K_n \quad (2.34)$$

## 8. Free outflow (seepage face)

In this case, drainage will only occur if the pressure head in the bottom compartment ( $h_n$ ) becomes larger than zero. During drainage and after a drainage event,  $h_n$  is set equal to zero and  $q_{\text{bot}}$  is calculated by solving the Richards equation. This option is commonly applied for lysimeters, where outflow only occurs when the lowest part of the lysimeter becomes saturated. In the field this condition is appropriate when the soil profile is drained by a coarse gravel layer. Lysimeters with groundwater table controlling provisions can also be simulated imposing a zero bottom flux condition (SWBOTB=6), combined with a single drainage system, where the drainage resistance is low.

# 3 Evapotranspiration and rainfall interception

## 3.1 Introduction

In contrast to rainfall, accurate measurement of evapotranspiration fluxes is far from trivial. Evapotranspiration fluxes strongly vary with the local hydrological conditions. Therefore SWAP simulates evapotranspiration fluxes employing basic weather data or reference crop evapotranspiration data, as discussed in this chapter.

Rainfall and irrigation minus the sum of transpiration, evaporation and interception determine the amount of infiltration in the soil (Figure 3.1) and groundwater fluxes. In general the sums of rainfall+irrigation and transpiration+evaporation+interception are large compared to their difference, which equals the infiltration. This means that relative errors in these sums will magnify in relative errors of infiltration and groundwater fluxes. Therefore, reliable soil water and groundwater fluxes require accurate simulation of evapotranspiration and interception fluxes.

**Figure 3.1** Water fluxes near the soil surface.

more rapidly than transpiration fluxes. Water harvesting, by leaving fields fallow during one or several seasons, uses this phenomenon. Because of the different physical behaviour of transpiration and evaporation, SWAP will consider evaporation and transpiration separately.

In this chapter we will first discuss the rainfall interception as used for low vegetation and forests. Next we describe the simulation of potential evapotranspiration and its distribution into potential transpiration and evaporation for partly covered soils. Then we will discuss the reduction of transpiration for wet, dry and saline soil conditions, and the reduction of evaporation for dry top soils. In the last part the related model input is described.

In general the daily water fluxes passing through a canopy are large compared to the amounts of water stored in the canopy itself. Therefore we will assume that root water extraction in the soil is equal to plant transpiration. While root water extraction may occur throughout the root zone, soil evaporation occurs at the interface soil-atmosphere. The consequence is that during drying conditions, evaporation fluxes decline much

## 3.2 Rainfall interception

Two methods are available in SWAP to simulate rainfall interception: method Hoyningen-Braden for agricultural crops and method Gash for forests.

### 3.2.1 Method Hoyningen-Braden

For agricultural crops and for pasture, SWAP computes the interception following Von Hoyningen-Hüne (1983) and Braden (1985). They proposed the following general formula for canopy interception (Figure 3.2):

$$P_i = a \cdot LAI \left( 1 - \frac{1}{1 + \frac{b \cdot P_{\text{gross}}}{a \cdot LAI}} \right) \quad (3.1)$$

where  $P_i$  is intercepted precipitation ( $\text{cm d}^{-1}$ ),  $LAI$  is leaf area index,  $P_{\text{gross}}$  is gross precipitation ( $\text{cm d}^{-1}$ ),  $a$  is an empirical coefficient ( $\text{cm d}^{-1}$ ) and  $b$  represents the soil cover fraction (-). For increasing amounts of precipitation, the amount of intercepted precipitation asymptotically reaches the saturation amount  $aLAI$ . In principle  $a$  must be determined experimentally and should be specified in the input file. In case of ordinary agricultural crops we may assume  $a = 0.025 \text{ cm d}^{-1}$ . When  $LAI$  is given, SWAP estimates the soil cover fraction  $b$  as:

$$b = 1 - e^{-\kappa_{gr} LAI} \quad (3.2)$$

where  $\kappa_{gr}$  (-) is the extinction coefficient for solar radiation (see Par. 3.4).

**Figure 3.2** Interception for agricultural crops (Von Hoyningen-Hüne, 1983; Braden, 1985) and forests (Gash, 1979; 1985).

In case irrigation water is applied with sprinklers, SWAP will simulate separately interception of rainfall and irrigation. This is required because the solute concentration of both water sources may be different. Observed rainfall  $P_{\text{gross}}$  minus intercepted rainfall  $P_i$  is called net rainfall  $P_{\text{net}}$ . Likewise, applied irrigation depth  $I_{\text{gross}}$  minus intercepted irrigation water is called net irrigation depth  $I_{\text{net}}$ .

The method of Von Hoyningen-Hüne and Braden is based on daily precipitation values. Although rainfall amounts may be specified in smaller time steps, the interception will be based on daily amounts.

### 3.2.2 Method Gash

A main drawback of the method of Von Hoyningen-Hüne and Braden is that the effect of rain duration and evaporation during the rain event is not accounted for. In case of trees and forests, evaporation of intercepted water during rainfall can not be neglected. Gash (1979, 1985) formulated a physically based and widely used interception formula for forests. He considered rainfall to occur as a series of discrete events, each comprising a period of wetting up, a period of saturation and a period of drying out after the rainfall. The canopy is assumed to have sufficient time to dry out between storms. During wetting up, the increase of intercepted amount is described by:

$$\frac{\partial P_i}{\partial t} = (1 - p - p_t) P_{\text{mean}} - \frac{P_i}{S} E_{\text{mean}} \quad (3.3)$$

where  $p$  is a free throughfall coefficient (-),  $p_t$  is the proportion of rainfall diverted to stemflow (-),  $P_{\text{mean}}$  is the mean rainfall rate ( $\text{mm h}^{-1}$ ),  $E_{\text{mean}}$  is the mean evaporation rate of intercepted water when the canopy is saturated ( $\text{mm h}^{-1}$ ) and  $S$  is the maximum storage of intercepted water in the canopy (mm). Integration of Eq. (3.3) yields the amount of rainfall which saturates the canopy,  $P_s$  (mm):

$$P_s = -\frac{P_{\text{mean}} S}{E_{\text{mean}}} \ln \left( 1 - \frac{E_{\text{mean}}}{P_{\text{mean}} (1 - p - p_t)} \right) \quad \text{with} \quad 1 - \frac{E_{\text{mean}}}{P_{\text{mean}} (1 - p - p_t)} \geq 0 \quad (3.4)$$

For small storms ( $P_{\text{gross}} < P_s$ ) the interception can be calculated from:

$$P_i = (1 - p - p_t) P_{\text{gross}} \quad (3.5)$$

For large storms ( $P_{\text{gross}} > P_s$ ) the interception according to Gash (1979) follows from:

$$P_i = (1 - p - p_t) P_s + \frac{E_{\text{mean}}}{P_{\text{mean}}} (P_{\text{gross}} - P_s) \quad (3.6)$$

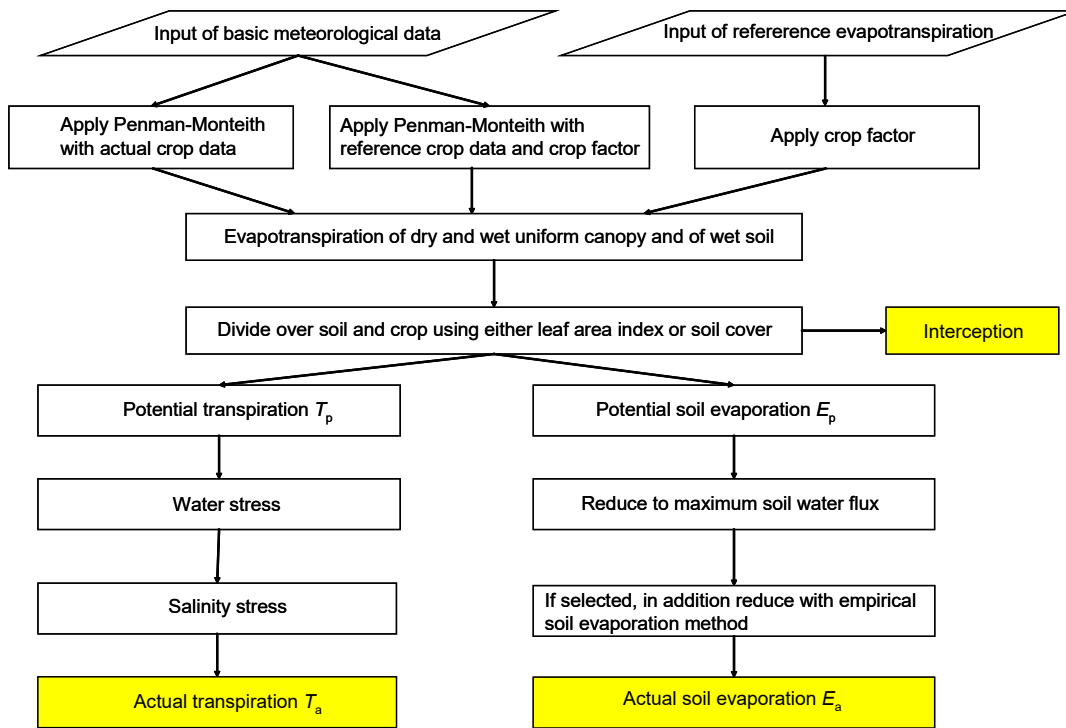

Figure 3.2 shows the relation of Gash for typical values of a pine forest as function of rainfall amounts. The slope  $\partial P_i / \partial P_{\text{gross}}$  before saturation of the canopy equals  $(1 - p - p_t)$ , after saturation of the canopy this slope equals  $E_{\text{mean}} / P_{\text{mean}}$ .

SWAP uses mean intensities of rainfall and evaporation rate to calculate the amount of rainfall which saturates the canopy, according to Eq. (3.4). Next, depending on the total amount of rainfall during a day, the amount of interception is calculated according to either Eq. (3.5) or Eq. (3.6).

## 3.3 Potential evapotranspiration of uniform surfaces

Evapotranspiration refers to both *transpiration* of the plants and *evaporation* of the soil or of water intercepted by vegetation or ponding on the soil surface. The addition 'potential' refers to non-limiting soil conditions. The potential evapotranspiration flux is therefore only determined by atmospheric conditions and plant characteristics. In SWAP we assume the atmospheric conditions to be external conditions, which are representative for the area for which the simulations are performed.

Starting point in the calculations is the determination of the potential evapotranspiration of different uniform surfaces. The model offers two methods to calculate this potential evapotranspiration (see Figure 3.3): the Penman-Monteith method and the reference evapotranspiration method. Both methods can be combined with crop factors; Penman-Monteith can also be applied without crop factors.

**Figure 3.3** Method used in SWAP to derive actual transpiration and soil evaporation of partly covered soils from basic input data.

### 3.3.1 Penman Monteith method

Using similar physics as Penman (1948), Monteith (1965) derived an equation that describes the evapotranspiration from a dry, uniform, vegetated surface, which is optimally supplied with water. This equation is known as the Penman-Monteith equation. Jensen et al. (1990) analyzed the performance of 20 different evapotranspiration formula using lysimeter data of 11 stations around the world under different climatic conditions. The Penman-Monteith formula ranked as the best for all climatic conditions. Therefore this equation has become an international standard for calculation of potential evapotranspiration (Allen et al., 1998), and is applied by SWAP.

For a closed canopy with insignificant evaporation from the soil the Penman-Monteith equation can be written as (Monteith, 1965, 1981):

$$ET_p = \frac{\frac{\Delta_v}{\lambda_w} (R_n - G) + \frac{p_1 \rho_{air} C_{air}}{\lambda_w} \frac{e_{sat} - e_a}{r_{air}}}{\Delta_v + \gamma_{air} \left( 1 + \frac{r_{crop}}{r_{air}} \right)} \quad (3.7)$$

where  $ET$  is the transpiration rate of the canopy ( $\text{mm d}^{-1}$ ),  $\Delta_v$  is the slope of the vapour pressure curve ( $\text{kPa } ^\circ\text{C}^{-1}$ ),  $\lambda_w$  is the latent heat of vaporization ( $\text{J kg}^{-1}$ ),  $R_n$  is the net radiation flux at the canopy surface ( $\text{J m}^{-2} \text{d}^{-1}$ ),  $G$  is the soil heat flux ( $\text{J m}^{-2} \text{d}^{-1}$ ),  $p_1$  accounts for unit conversion ( $=86400 \text{ s d}^{-1}$ ),  $\rho_{air}$  is the air density ( $\text{kg m}^{-3}$ ),  $C_{air}$  is the heat capacity of moist air ( $\text{J kg}^{-1} \text{ } ^\circ\text{C}^{-1}$ ),  $e_{sat}$  is the saturation vapour pressure (kPa),  $e_a$  is the actual vapour pressure (kPa),  $\gamma_{air}$  is the psychrometric constant ( $\text{kPa } ^\circ\text{C}^{-1}$ ),  $r_{crop}$  is the crop resistance ( $\text{s m}^{-1}$ ) and  $r_{air}$  is the aerodynamic resistance ( $\text{s m}^{-1}$ ).

The FAO has proposed a clearly defined and well established methodology to apply the Penman-Monteith equation for evapotranspiration estimates at a daily time scale using routinely measured weather data (Allen et al., 1998). The required weather data include daily values of air temperature (preferably the minimum as well as the maximum value), global radiation, wind speed and relative humidity. The FAO methodology is applied in SWAP and the basic equations are listed in Appendix 1.

In general the parameter  $r_{\text{crop}}$  is used to calculate  $ET_p$  from a mixture of vegetation and bare soil, in which case this parameter is called the surface resistance  $r_s$ . When crop factors are used, SWAP applies the Penman-Monteith method to either vegetations fully covering the soil or bare soils. Therefore we replace  $r_s$  by  $r_{\text{crop}}$  (at bare soils  $r_{\text{crop}}$  is absent and equals zero). SWAP calculates fluxes for three uniform surfaces:

- $ET_{w0}$  ( $\text{cm d}^{-1}$ ), evapotranspiration rate of a closed wet canopy;
- $ET_{p0}$  ( $\text{cm d}^{-1}$ ), evapotranspiration rate of a closed dry canopy;
- $E_{p0}$  ( $\text{cm d}^{-1}$ ), evaporation rate from a wet, bare soil.

These ET-quantities are obtained by varying the values for crop resistance ( $r_{\text{crop}}$ ), crop height ( $h_{\text{crop}}$ ) and reflection coefficient ( $\alpha_r$ ) for the three uniform surfaces as listed in Table 3.1. For a dry crop completely covering the soil with optimal water supply in the soil  $r_{\text{crop}}$  is minimal and varies between  $30 \text{ s m}^{-1}$  for arable crop to  $150 \text{ s m}^{-1}$  for trees in a forest (Allen et al., 1986, 1989). This value is input, as is the crop height. For a wet, bare soil SWAP will assume  $r_{\text{crop}} = 0$  and 'crop height'  $h_{\text{crop}} = 0.1 \text{ cm}$ .

As Figure 3.3 shows, the Penman-Monteith method can be applied for the reference grass, in combination with crop factors. This method has been extensively discussed by Allen et al., (1998). In that case SWAP will set  $r_{\text{crop}} = 70 \text{ s m}^{-1}$ ,  $h_{\text{crop}} = 12 \text{ cm}$  and  $\alpha_r = 0.23$ , as generally defined for the reference grass. Table 3.2 shows how the crop factors relate  $ET_{w0}$  and  $ET_{p0}$  to the corresponding values for grass. The crop factors belong to a certain crop and depend on its development stage. In case of bare soils the 'crop factor' has just one value, and is called soil factor. The use of a soil factor is optional. Without soil factor SWAP will directly calculate  $E_{p0}$  with the Penman-Monteith method. With soil factor SWAP will relate  $E_{p0}$  to the reference evapotranspiration rate calculated with Penman-Monteith for grass,  $ET_{p0,\text{grass}}$ . For ponding conditions potential evaporation is related to the potential evaporation of intercepted water (see Table 3.2).

**Table 3.1** Three uniform surfaces and its corresponding potential evapotranspiration  $ET_p$  : parameter settings for the method Penman-Monteith.

Description of uniform surface	$ET_p$	$r_{\text{crop}}$ ( $\text{s m}^{-1}$ )	$h_{\text{crop}}$ (cm)	$\alpha_r$ (-)
wet canopy, completely covering the soil	$ET_{w0}$	input	input	input
dry canopy completely covering the soil	$ET_{p0}$	input	input	input
wet, bare soil	$E_{p0}$	0.0	0.1	0.15

**Table 3.2** Options in SWAP to derive potential evapotranspiration rates for uniform surfaces.

Uniform surface	Input $ET_{\text{ref}}$	Input basic weather data, use PM	
		Reference grass	Actual crop
Wet canopy	$ET_{w0} = k_c ET_{\text{ref}}$	$ET_{w0} = k_c ET_{w0,\text{grass}}$	$ET_{w0}$
Dry canopy	$ET_{p0} = k_c ET_{\text{ref}}$	$ET_{p0} = k_c ET_{p0,\text{grass}}$	$ET_{p0}$
Bare soil	Use soil factor	$E_{p0} = k_{\text{soil}} ET_{\text{ref}}$	$E_{p0} = k_{\text{soil}} ET_{p0,\text{grass}}$
	No soil factor	$E_{p0} = ET_{\text{ref}}$	$E_{p0}$
Ponding layer	$E_{p0} = k_{\text{pond}} ET_{\text{ref}}$	$E_{p0} = ET_{w0}$	$E_{p0} = ET_{w0}$

### 3.3.2 Reference evapotranspiration and crop factors

Application of the Penman-Monteith equation requires daily values of air temperature, net radiation, wind speed and air humidity, which data might not be available. Also in some studies other methods than Penman-Monteith might be more appropriate. For instance in The Netherlands the Makkink equation is widely used (Makkink, 1957; Feddes, 1987). Therefore SWAP allows the use of a reference evapotranspiration rate  $ET_{ref}$  ( $\text{cm d}^{-1}$ ) (Figure 3.3). In that case the potential evapotranspiration rate for the dry canopy  $ET_{p0}$  is calculated by:

$$ET_{p0} = k_c ET_{ref} \quad (3.8)$$

where  $k_c$  is the so called crop factor, which depends on the crop type and the method employed to obtain  $ET_{ref}$ . In a similar way the potential evapotranspiration rate for the wet canopy  $ET_{w0}$  is derived:

$$ET_{w0} = k_c ET_{ref} \quad (3.9)$$

The evaporation rate of a wet, bare soil, can be derived with a soil factor  $k_{soil}$  :

$$E_{p0} = k_{soil} ET_{ref} \quad (3.10)$$

Without soil factor,  $E_{p0}$  is set equal to  $ET_{ref}$ . For ponding conditions a separate factor  $k_{pond}$  is used. Table 3.2 provides an overview of the SWAP options when  $ET_{ref}$  and crop, soil and pond factors are used.

The reference evapotranspiration rate can be determined in several ways, such as pan evaporation, the Penman open water evaporation (Penman, 1948), the FAO modified Penman equation (Doorenbos and Pruitt, 1977), the Penman-Monteith equation applied for a reference crop (Allen et al., 1998), Priestly-Taylor (1972), Makkink (Makkink, 1957; Feddes, 1987) or Hargreaves et al. (1985). In case of Priestly-Taylor and Makkink, only air temperature and solar radiation data are required. Hargreaves requires solely air temperature data.

In SWAP the crop factors are used to convert the evapotranspiration rate of a reference crop fully covering the soil to the potential evapotranspiration rate of the actual crop fully covering the soil (Figure 3.3). This is different from programs like CROPWAT (Smith, 1992) and CRIWAR (Bos et al., 1996), which use crop factors that depend on the crop development stage and soil cover. Because the soil has generally a dry top layer, soil evaporation is usually below the potential evaporation rate. Hence, these crop factors semi-empirically combine the effect of an incomplete soil cover and reduced soil evaporation. Instead SWAP uses the crop factor to relate uniform, cropped surfaces. Therefore crop factors in SWAP can be larger than those in CROPWAT and CRIWAR.

## 3.4 Potential transpiration and evaporation fluxes of partly covered soils

For accurate agrohydrological analysis we need the distribution of the atmospheric demand over potential transpiration and potential evaporation. This is important for proper simulation of crop growth and root uptake of nutrients and salts, which depend on the reduction of transpiration only, and for proper simulation of actual evaporation and transpiration fluxes. SWAP offers two methods for this distribution:

1. Distribution based on crop and soil factors
2. Distribution based on direct application of Penman-Monteith

### 3.4.1 Distribution based on crop and soil factors

The application of crop and soil factors as described in Par. 3.3 yields fluxes of uniform surfaces: either a wet ( $ET_{w0}$ ) or dry ( $ET_{p0}$ ) canopy and a wet soil ( $E_{p0}$ ). These uniform fluxes are used to derive the potential transpiration rate  $T_p$  and potential soil evaporation rate  $E_p$  for partly covered soils.

When the crop is wet due to interception, SWAP assumes that the energy available for evapotranspiration is entirely used to evaporate the intercepted water, independent of the soil cover fraction. This is at least

valid for higher soil cover fractions. At small soil cover fractions, this assumption might overestimate the actual evaporation rate of intercepted water. However, as at small soil fractions the interception amounts are minor, this seems not important. The fraction of the day that the crop is wet,  $W_{\text{frac}}$  (-), therefore follows from the ratio of the daily amount of intercepted precipitation  $P_i$  (Par. 3.2) and  $ET_{w0}$ :

$$W_{\text{frac}} = \frac{P_i}{ET_{w0}} \quad \text{with} \quad W_{\text{frac}} \leq 1.0 \quad (3.11)$$

Next the potential soil evaporation rate can be derived from  $E_{p0}$ , taking into account reductions due to shadow by crops and periods without evaporation when the crop is wet. The most common method assumes that the net radiation inside the canopy decreases according to an exponential function (Goudriaan, 1977; Belmans, 1983). In that case, the potential soil evaporation rate  $E_p$  is equal to:

$$E_p = E_{p0} (1 - W_{\text{frac}}) e^{-\kappa_{\text{gr}} LAI} \quad (3.12)$$

where  $\kappa_{\text{gr}}$  (-) is the extinction coefficient for solar radiation. Ritchie (1972) and Feddes (1978) used  $\kappa_{\text{gr}} = 0.39$  for common crops. More recent approaches estimate  $\kappa_{\text{gr}}$  as the product of the extinction coefficient for diffuse visible light,  $\kappa_{\text{df}}$  (-), which varies with crop type from 0.4 to 1.1, and the extinction coefficient for direct visible light,  $\kappa_{\text{dir}}$  (-):

$$\kappa_{\text{gr}} = \kappa_{\text{df}} \kappa_{\text{dir}} \quad (3.13)$$

Sometimes reliable figures of LAI as function of crop development are lacking. For such cases, the soil cover fraction is a practical alternative to account for the reduction of solar radiation due to crop cover:

$$E_p = E_{p0} (1 - W_{\text{frac}}) (1.0 - SC) \quad (3.14)$$

Next the most important evapotranspiration term should be calculated: the potential transpiration rate  $T_p$  of the dry crop which partly covers the soil. During transpiration of dry crops, the total energy for evapotranspiration will be distributed over  $E_p$  and  $T_p$ . SWAP assumes that the total evapotranspiration rate in periods with dry canopy corresponds to  $ET_{p0}$ , as this rate is best defined. Therefore  $T_p$ , taking into account rainfall interception and partly soil cover, follows from:

$$T_p = ET_{p0} (1.0 - W_{\text{frac}}) - E_p \quad (3.15)$$

### 3.4.2 Distribution based on direct application of Penman-Monteith

In the PM-direct method, crop or soil factors to translate reference ET to crop ET are no longer needed. In this way the cumbersome calibration of crop and soil factors during the growing season is avoided, and the method can be made climate proof if used in combination with an adequate crop growth model. The method requires biophysical data on leaf area index, albedo, crop height, minimal stomatal resistance and minimal soil resistance.

In the PM-direct method as implemented in SWAP we assume that during the fraction of time that the crop is wet,  $W_{\text{frac}}$ , the transpiration is suppressed due to the fact that the interception evaporation has a very low resistance, creating a near-saturated atmosphere around the leaves. The potential transpiration of a dry canopy  $T_p$  ( $\text{mm d}^{-1}$ ) and potential evaporation  $E_p$  ( $\text{mm d}^{-1}$ ) of the actual crop are thus calculated directly with:

$$T_p = \frac{(1 - W_{\text{frac}}) \left( V_c \frac{\Delta_v}{\lambda_w} (R_n - G) + \frac{p_i \rho_a C_a}{\lambda_w} \left( \frac{e_{\text{sat}} - e_a}{r_{a, \text{can}}} \right) \right)}{\Delta_v + \gamma_a \left( 1 + \frac{r_{s, \text{min}}}{r_{a, \text{can}} LAI_{\text{eff}}} \right)} \quad (3.16)$$

$$E_p = \frac{(1.0 - V_c) \frac{\Delta_v}{\lambda_w} (R_n - G) + \frac{p_i \rho_a C_a}{\lambda_w} \left( \frac{e_{\text{sat}} - e_a}{r_{a, \text{soil}}} \right)}{\Delta_v + \gamma_a \left( 1.0 + \frac{r_{\text{soil}}}{r_{a, \text{soil}}} \right)} \quad (3.17)$$

where  $W_{\text{frac}}$  is the fraction of the day in which the canopy is wet (-),  $V_c$  is vegetation cover (-),  $r_{s, \text{min}}$  is the minimal stomatal resistance ( $\text{s m}^{-1}$ ),  $LAI_{\text{eff}}$  is the effective leaf area index (-) and  $r_{\text{soil}}$  is the soil resistance of a wet soil ( $\text{s m}^{-1}$ ). Note that instead of the overall crop resistance, Eq. (3.16) uses the minimal stomatal resistance which is corrected with  $LAI_{\text{eff}}$ .

The vegetation cover is based on solar light extinction within a canopy:

$$V_c = 1 - e^{-\kappa_{\text{dir}} \kappa_{\text{dif}} LAI} \quad (3.18)$$

where  $\kappa_{\text{dir}}$  and  $\kappa_{\text{dif}}$  are the extinction coefficients for direct and diffuse solar light, respectively (-) and  $LAI$  is the actual leaf area index (-).

$LAI_{\text{eff}}$  is related to the stomata that participate in transpiration and is derived from the actual leaf area index  $LAI$  with (Bastiaanssen et al., 2012):

$$LAI_{\text{eff}} = \frac{LAI}{0.3 LAI + 1.2} \quad (3.19)$$

The aerodynamic resistances are first calculated for uniform crop and soil surfaces according to Allen et al. (1998). Next these resistances are corrected for the vegetation cover:

$$r_{a, \text{can}} = \frac{r_{a, \text{can}, 0}}{V_c} \quad (3.20)$$

$$r_{a, \text{soil}} = \frac{r_{a, \text{soil}, 0}}{1 - V_c} \quad (3.21)$$

where  $r_{a, \text{can}, 0}$  and  $r_{a, \text{soil}, 0}$  are the aerodynamic resistances of uniform crop and soil surfaces.

For the interception evaporation of a wet crop,  $E_i$ , we apply Eq. (3.16) with a lower value of the minimal stomatal resistance than for a dry crop, with the default value set to zero. The fraction of a day that the canopy is wet is then calculated as:

$$W_{\text{frac}} = \frac{P_i}{E_i} \quad (3.22)$$

where  $P_i$  is the rainfall interception ( $\text{mm d}^{-1}$ ) and  $E_i$  is the evaporation flux of a wet canopy ( $\text{mm d}^{-1}$ ).

On a daily base, the soil heat flux  $G$  is assumed to be negligible.

## 3.5 Actual plant transpiration

### 3.5.1 General approach

The potential transpiration and evaporation fluxes ( $T_p$  and  $E_p$ ) as described in Par. 3.4 are based on atmospheric conditions and vegetation properties, assuming favourable soil moisture conditions. In this paragraph we describe the reduction of root water uptake and thus transpiration due to oxygen stress and drought stress. In Par. 3.6 the reduction of soil evaporation due to drying of the top soil is described. Paragraph 8.6 considers the effect of high salt concentrations on root water uptake and Par. 10.2 the effect of frozen soils. Ultimately the calculations yield the actual transpiration and evaporation fluxes ( $T_a$  and  $E_a$ ) as depicted in Figure 3.3.

The maximum possible root water extraction rate, integrated over the rooting depth, should equal  $T_p$  ( $\text{cm d}^{-1}$ ). Taking into account the root length density distribution (Bouten, 1992), the potential root water extraction rate at a certain depth,  $S_p(z)$  ( $\text{d}^{-1}$ ) can be calculated by:

$$S_p(z) = \frac{\ell_{\text{root}}(z)}{\int_{-D_{\text{root}}}^0 \ell_{\text{root}}(z) dz} T_p \quad (3.23)$$

where  $D_{\text{root}}$  is the root layer thickness (cm).

These potential fluxes to the roots are reduced due to suboptimal soil conditions: too wet, too dry, too saline or too cold. SWAP determines stress factors for these factors at each soil compartment. In case of combined water and salt stress, Skaggs et al. (2006) argue that the stress factors for water and salt stress can be multiplied. In SWAP we follow this multiplication approach for all stresses and calculate the actual root water flux,  $S_a(z)$  ( $d^{-1}$ ), as:

$$S_a(z) = \alpha_{rw} \alpha_{rd} \alpha_{rs} \alpha_{rf} S_p(z) \quad (3.24)$$

where  $\alpha_{rd}$  (-),  $\alpha_{rw}$  (-),  $\alpha_{rs}$  (-) and  $\alpha_{rf}$  (-) are the reduction factors for conditions which are too wet, too dry, too saline, or too cold, respectively.

Integration of  $S_a(z)$  over the root layer yields the actual transpiration rate  $T_a$  ( $cm\ d^{-1}$ ):

$$T_a = \int_{-D_{root}}^0 S_a(z) \partial z \quad (3.25)$$

In many applications the proportion of occurring stress factors is relevant information. Therefore SWAP will split the total transpiration reduction into individual contributions of the occurring stress factors by multiplying  $(S_p(z)-S_a(z))$  with the proportion of the logarithmic value of each of the reduction factors  $\log(\alpha_j) / \sum_{i=1} \log(\alpha_i)$ .

### 3.5.2 Feddes function for root water uptake

Stresses due to dry or wet conditions and/or high salinity concentrations may reduce  $S_p(z)$ . The water stress in SWAP is described by the function proposed by Feddes et al. (1978), which is depicted in Figure 3.4. In the range  $h_3 < h < h_2$  root water uptake is optimal. Below  $h_3$  root water uptake linearly declines due to drought until zero at  $h_4$  (wilting point). The critical pressure head  $h_3$  increases for higher potential transpiration rates  $T_p$ . Above  $h_2$  root water uptake linearly declines due to insufficient aeration until zero at  $h_1$ , i.e. representing threshold values for minimum and maximum oxygen deficiency.

**Figure 3.4** Reduction coefficient for root water uptake,  $\alpha_{rw}$ , as function of soil water pressure head  $h$  and potential transpiration rate  $T_p$  (after Feddes et al., 1978).

Sometimes only some parts of the root zone are stressed and show reduction of root water uptake, while other parts have favourable conditions for root water uptake. In these conditions the reduction in the stressed parts might be compensated by extra root water uptake in the parts with favourable conditions. This compensation was not part of the original Feddes reduction function. In SWAP the user might add this compensation to the Feddes function. The compensation concept implemented has been described by Jarvis (1989; 2011).

Constant critical pressure heads for oxygen stress seem not realistic, as oxygen stress depends on various abiotic and biotic factors. Therefore, as alternative the process-based method of Bartholomeus et al. (2008) has been implemented (Par. 3.5.3). At the dry side, the input values for  $h_{3l}$  and  $h_{3h}$  depend on plant type, soil texture, root density and atmospheric demand, input values which are not commonly available. Also the linear decline of the reduction factor in the range  $h_4 < h < h_3$  may deviate from reality. Therefore also a detailed, microscopic root water uptake module for drought has been added to SWAP (Par. 3.5.4).

### 3.5.3 Detailed oxygen stress

When the availability of oxygen or water is insufficient to meet the metabolic demands of plants for these resources, the plant suffers from oxygen and drought stress, respectively. The first physiological process inhibited at oxygen stress (resulting from high soil moisture contents) is plant root respiration, i.e. oxygen consumption in the roots, a process that increases with rising temperatures. High soil

moisture contents hamper oxygen transport from the atmosphere, through the soil - where part of the oxygen is additionally consumed by soil microorganisms - and to the root cells. Reduced respiration negatively affects the energy supply to plant metabolism (Bartholomeus et al. 2011).

Root respiration is determined by interacting respiratory (i.e. oxygen consuming) and diffusive (i.e. oxygen providing) processes in and to the soil. Plant roots respire at a potential rate under optimal soil aeration and thus non-limiting oxygen availability. This potential root respiration is in equilibrium with the oxygen demand of plant roots, which is determined by plant characteristics and soil temperature (as simulated with SWAP). Upon increasingly wetter conditions, however, the gas-filled porosity of the soil decreases and oxygen availability becomes insufficient for potential root respiration. Daily respiration reduction (i.e. potential minus actual respiration) is calculated with a model for oxygen transport and consumption, which uses generally applied physiological and physical relationships to calculate both the oxygen demand of, and the oxygen supply to plant roots (Figure 3.5). For details and equations of the implemented method we refer to Bartholomeus et al. (2008).

**Figure 3.5** Schematization of the oxygen module used to simulate daily respiration reduction. The model combines interacting physiological processes (i.e. root respiration and microbial respiration) and physical processes (i.e. macro-scale and micro-scale oxygen diffusion) (figure from Bartholomeus et al. 2011). Details of equations involved are given in Bartholomeus et al. (2008).

Simulation of the actual root respiration for a crop requires actual data on soil type, daily soil temperature and daily gas-filled porosity in each soil layer. The latter two variables are simulated within SWAP. Simulation of soil temperature should thus be switched on. The model of Bartholomeus et al. (2008) is applied to all soil layers of SWAP, to account for layer-specific soil physical properties, moisture contents and temperatures. The difference between potential and actual root respiration is calculated for each soil layer separately. Subsequently, the reduction coefficient  $\alpha_{rw}$  due to oxygen stress is calculated for each soil layer, based on the assumption that root water uptake is proportional to growth respiration.

The latter assumption is supported by several arguments (Bartholomeus et al. 2008). If stomata are fully opened, root water uptake is optimal ( $\alpha_{rw} = 1$ ) and dominated by hydraulic forces. At fully open stomata, potential photosynthesis is achieved and oxygen is needed for both maintenance and growth respiration. Potential root water uptake is thus only possible as long as there is no oxygen stress. Oxygen stress induces stomatal closure (e.g. Glinski and Stepniewski, 1985; Kramer, 1951). At complete stomatal closure, the actual transpiration and photosynthesis approach zero ( $\alpha_{rw} = 0$ ). In that case, oxygen is solely used for maintenance respiration.

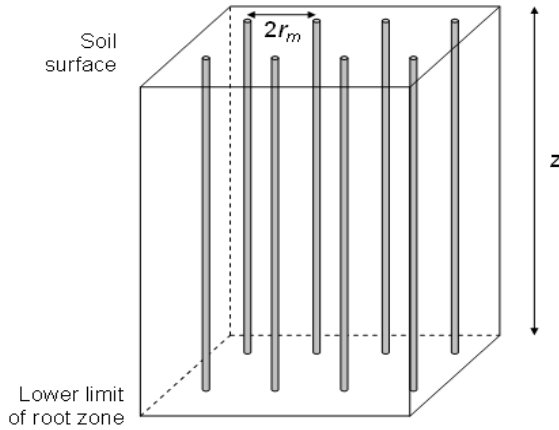

Between the limits  $\alpha_{rw} = 1$  and  $\alpha_{rw} = 0$ , it is assumed that the reduction of root water uptake is directly proportional to the reduction in root respiration. Kamaluddin and Zwiazek (2001)

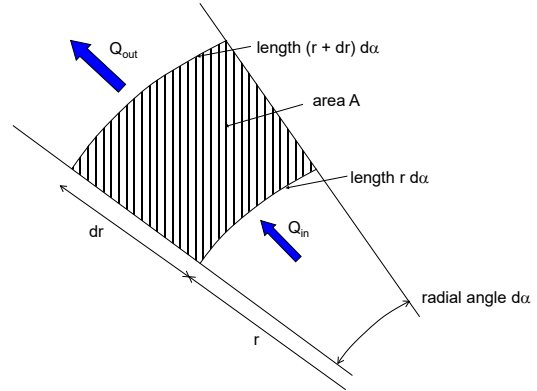

demonstrated, by inhibition of the metabolism of the roots, that a positive correlation between root respiration and water uptake exists. This implies a gradual decrease of root water uptake with increased oxygen stress (Bartholomeus et al. 2008).

### 3.5.4 Detailed drought stress

In contrast to the macroscopic Feddes model as described in Par. 3.5.2, microscopic models describe the radial flow of soil water towards individual roots. The roots are considered as linear tubes. The root system as a whole is considered as a set of such individual tubes, regularly spaced in the soil at definable distances (Figure 3.6). The density of the tubes with depth may vary, similar to root density in a root zone.

**Figure 3.6** Schematization of root system by equally spaced tubes. Density in the vertical may differ.

**Figure 3.7** Water balance of a radial segment.

In such a geometry, a radial flow pattern towards the roots exists. Figure 3.7 depicts this flow pattern for a segment with angle  $d\alpha$  (rad). The inflow  $Q_{in}$  ( $m^2 d^{-1}$ ) can be written as:

$$Q_{in} = q r d\alpha \quad (3.26)$$

and the outflow  $Q_{out}$  ( $m^2 d^{-1}$ ) equals:

$$Q_{out} = \left( q + \frac{\partial q}{\partial r} dr \right) (r + dr) d\alpha \quad (3.27)$$

where  $q$  ( $m d^{-1}$ ) is the soil water flux density and  $r$  (m) is the radial distance from the root centre. Calculation of the terms of Eq. (3.27) and subsequently the difference  $Q_{in} - Q_{out}$  yields:

$$Q_{in} - Q_{out} = -d\alpha \left[ q dr + r \frac{\partial q}{\partial r} dr + \frac{\partial q}{\partial r} (dr)^2 \right] \quad (3.28)$$

The segment area  $A$  ( $\text{m}^2$ ) between radial distances  $r$  and  $r + dr$  (m) from the root centre is equal to:

$$A = \pi(r + dr)^2 \frac{d\alpha}{2\pi} - \pi r^2 \frac{d\alpha}{2\pi} = \left( r dr + \frac{dr^2}{2} \right) d\alpha \quad (3.29)$$

As we are dealing with infinite small differences, we may omit higher order terms with respect to first order terms: the third term in Eq. (3.28), and the second term in Eq. (3.29). The water balance of segment  $A$  can be written with the simplified equations (3.28) and (3.29) as:

$$\frac{\partial \theta}{\partial t} A = Q_{in} - Q_{out} \quad \rightarrow \quad \frac{\partial \theta}{\partial t} r dr d\alpha = -d\alpha \left[ q dr + r dr \frac{\partial q}{\partial r} \right] \quad (3.30)$$

where  $\theta$  is the volumetric water content ( $\text{m}^3 \text{m}^{-3}$ ) and  $t$  is the time (d). Therefore we may write the water balance of the radial flow pattern towards root as:

$$\frac{\partial \theta}{\partial t} = -\frac{q}{r} - \frac{\partial q}{\partial r} \quad (3.31)$$

The soil water flux itself can be described by the Darcy equation without the gravity component:

$$q = -k \frac{\partial h}{\partial r} \quad (3.32)$$

where  $k$  is hydraulic conductivity and  $h$  is soil water pressure head (cm).

When we solve Eq. (3.32) using realistic values for extraction rates and soil hydraulic properties, we get very strong gradients  $\partial h / \partial r$  near the root surface. This is caused by the rapid decline of the hydraulic conductivity at lower  $h$  values and by the increasing flux density due to converging flow lines near the roots. In order to solve Eq. (3.31) numerically, in the past gross simplifications were required. However, Eq. (3.31) can be solved more accurately when we use the matric flux potential as driving variable, instead of the soil water pressure head. The matric flux potential  $M$  ( $\text{m}^2 \text{d}^{-1}$ ) is defined as:

$$M = \int_{h_w}^h k(h) dh \quad (3.33)$$

where  $h_w$  is the pressure head corresponding to plant wilting point. With the matric flux potential we can simplify the Darcy equation:

$$q = -k \frac{\partial h}{\partial r} = -\frac{\partial M}{\partial r} \quad (3.34)$$

When we numerically solve Eq. (3.31) with the matric flux potential, resulting  $M(r)$  profiles are much more linear than  $h(r)$  profiles, which is a consequence of the linear character of Eq. (3.34). Use of the matric flux potential yields even analytical solutions for microscopic root water extraction, which was a prerequisite for use in ecohydrological models as SWAP. De Jong van Lier et al. (2008) describe the analytical solution in detail, and did upscale the microscopic approach to entire root zones with variable root densities and soil moisture conditions. In a later paper (De Jong van Lier et al., 2013) the authors extended the microscopic concept in the soil with radial and axial hydraulic resistances within the plant system. The approach of De Jong van Lier et al. (2013) been implemented in SWAP. For detailed theoretical background and applications we refer to both papers.

### 3.6 Actual soil evaporation

At a wet soil, soil evaporation equals its potential rate  $E_p$ . This is also the case at ponded conditions, during which SWAP will increase  $E_p$  to the evaporation rate of intercepted water with or without a ponding factor (Table 3.2). When the soil becomes drier, the soil hydraulic conductivity decreases, which may reduce  $E_p$  to evaporation rate,  $E_a$  (cm d<sup>-1</sup>). In SWAP the maximum evaporation rate that the top soil can sustain,  $E_{max}$  (cm d<sup>-1</sup>), is calculated according to Darcy's law:

$$E_{max} = K_{1/2} \left( \frac{h_{atm} - h_1 - z_1}{z_1} \right) \quad (3.35)$$

where  $K_{1/2}$  is the average hydraulic conductivity (cm d<sup>-1</sup>) between the soil surface and the first node,  $h_{atm}$  is the soil water pressure head (cm) in equilibrium with the air relative humidity,  $h_1$  is the soil water pressure head (cm) of the first node, and  $z_1$  is the soil depth (cm) at the first node. Equation (3.35) excludes water flow due to thermal differences in the top soil and due to vapour flow, as on daily basis the concerned flow amounts are probably negligible compared to isothermal, liquid water flow (Koorevaar et al., 1983; Ten Berge, 1986; Jury et al., 1991). Note that the value of  $E_{max}$  in Eq. (3.35) depends on the thickness of the top soil compartments. Increase of compartment thickness, generally results in smaller values for  $E_{max}$  due to smaller hydraulic head gradients. For accurate simulations at extreme hydrological conditions, the thickness of the top compartments should not be more than 1 cm (Van Dam and Feddes, 2000).

There is one serious limitation of the  $E_{max}$  procedure as described above.  $E_{max}$  is governed by the soil hydraulic functions  $\theta(h)$  and  $K(\theta)$ . It is still not clear to which extent the soil hydraulic functions, that usually represent a top layer of a few decimeters, are valid for the top few centimeters of a soil, which are subject to splashing rain, dry crust formation, root extension and various cultivation practices, including mulch additions. Therefore also empirical evaporation functions may be used, which require calibration of their parameters for the local climate, soil, cultivation and drainage situation. SWAP has the option to choose the empirical evaporation functions of Black (1969) or Boesten and Stroosnijder (1986).

#### Reduction of soil evaporation according to Black

Black (1969) calculated the cumulative actual evaporation during a drying cycle,  $\Sigma E_a$  (cm) as:

$$\Sigma E_a = \beta_1 t_{dry}^{1/2} \quad (3.36)$$

where  $\beta_1$  is a soil specific parameter (cm d<sup>-1/2</sup>), characterizing the evaporation process and  $t_{dry}$  is the time (d) after a significant amount of rainfall,  $P_{min}$ . SWAP resets  $t_{dry}$  to zero if the net precipitation  $P_{net}$  exceeds  $P_{min}$ .

#### Reduction of soil evaporation according to Boesten and Stroosnijder

**Figure 3.8** Evaporation fluxes according to Boesten and Stroosnijder (1986).

The Black-parameter  $\beta_1$  will be affected by the potential evaporation rates in the drying period. Therefore Boesten and Stroosnijder (1986) proposed to replace time by the sum of potential evaporation,  $\Sigma E_p$  (cm), as time variable (Figure 3.8):

$$\begin{aligned} \Sigma E_a &= \Sigma E_p & \text{for } \Sigma E_p &\leq \beta_2^2 \\ \Sigma E_a &= \beta_2 (\Sigma E_p)^{1/2} & \text{for } \Sigma E_p &> \beta_2^2 \end{aligned} \quad (3.37)$$

where  $\beta_2$  is a soil parameter ( $\text{cm}^{1/2}$ ), which should be determined experimentally. The parameter  $\beta_2$  determines the length of the potential evaporation period, as well as the slope of the  $\Sigma E_a$  versus  $(\Sigma E_p)^{1/2}$  relationship in the soil limiting stage.

Boesten and Stroosnijder suggest the following procedure with respect to updates of  $\Sigma E_p$ . On days with no excess in rainfall ( $P_{\text{net}} < E_p$ ),  $\Sigma E_p$  follows from Eq. (3.37):

$$(\Sigma E_p)^j = (\Sigma E_p)^{j-1} + (E_p - P_{\text{net}})^j \quad (3.38)$$

in which superscript  $j$  is the day number.  $(\Sigma E_a)^j$  is calculated from  $(\Sigma E_p)^j$  with Eq. (3.37) and  $E_a$  is calculated with

$$E_a^j = P_{\text{net}}^j + (\Sigma E_a)^j - (\Sigma E_a)^{j-1} \quad (3.39)$$

On days of excess in rainfall ( $P_{\text{net}} > E_p$ )

$$E_a^j = E_p^j \quad (3.40)$$

and the excess rainfall is subtracted from  $\Sigma E_a$

$$(\Sigma E_a)^j = (\Sigma E_a)^{j-1} - (P_{\text{net}} - E_p)^j \quad (3.41)$$

Next  $(\Sigma E_p)^j$  is calculated from  $(\Sigma E_a)^j$  with Eq. (3.37). If the daily rainfall excess is larger than  $(\Sigma E_p)^{j-1}$ , then both  $(\Sigma E_a)^j$  and  $(\Sigma E_p)^j$  are set to zero.

SWAP will determine  $E_a$  by taking the minimum value of  $E_p$ ,  $E_{\text{max}}$  and, if selected by the user, one of the empirical functions.

### 3.7.1 General information

Box 3.1 General information on meteorological input in main file \*.SWP.

```
*** METEOROLOGY SECTION ***

*****
* General data

* File name
  METFIL = 'Hupsel' ! File name of meteorological data without extension .YYY, [A200]
                    ! Extension is equal to last 3 digits of year, e.g. 003 denotes year 2003

* Type of weather data for potential evapotranspiration
  SWETR = 0          ! 0 = Use basic weather data and apply Penman-Monteith equation
                    ! 1 = Use reference evapotranspiration data in combination with crop factors

* If SWETR = 0, specify:
  LAT = 52.0         ! Latitude of meteo station [-90..90 degrees, R, North = +]
  ALT = 10.0         ! Altitude of meteo station [-400..3000 m, R]
  ALTW = 10.0        ! Height of wind speed measurement above soil surf. (10 m is default) [0..99 m, R]
  ANGSTROMA = 0.25   ! Fraction of extrater. radiation reaching the earth on overcast days [0..1 -, R]
  ANGSTROMB = 0.50   ! Add. fraction of extrater. radiation reaching the earth on clear days [0..1 -, R]
  SWDIVIDE = 1       ! 0 = Distribution E and T based on crop and soil factors
                    ! 1 = Distribution E and T based on direct application of Penman-Monteith

* Time interval of evapotranspiration and rainfall weather data
  SWMETDETAIL = 0    ! 0 = time interval is equal to one day
                    ! 1 = time interval is less than one day

* In case of detailed meteorological weather records (SWMETDETAIL = 1), specify:
  NMETDETAIL = 10    ! Number of weather data records each day [1..96 -, I]

* In case of daily meteorological weather records (SWMETDETAIL = 0):
  SWETSINE = 0       ! Switch, distribute daily Tp and Ep according to sinus wave [Y=1, N=0]

  SWRAIN = 0         ! Switch for use of actual rainfall intensity (only if SWMETDETAIL = 0):
                    ! 0 = Use daily rainfall amounts
                    ! 1 = Use daily rainfall amounts + mean intensity
                    ! 2 = Use daily rainfall amounts + duration
                    ! 3 = Use detailed rainfall records (dt < 1 day), as supplied in separate file

* If SWRAIN = 1, specify mean rainfall intensity RAINFLUX [0.d0..1000.d0 mm/d, R]
* as function of Julian time TIME [0..366 d, R], maximum 30 records
  TIME    RAINFLUX
  1.0     20.0
  360.0   20.0
* End of table

* If SWRAIN = 3, specify file name of file with detailed rainfall data
  RAINFIL = 'WagRain' ! File name of detailed rainfall data without extension .YYY, [A200]
                    ! Extension is equal to last 3 digits of year, e.g. 003 denotes year 2003
*****
```

Box 3.1 lists the general input data with respect to evapotranspiration. The name of the meteorological files is generic, and the extension denotes the year. A main choice is whether pre-calculated  $ET_{ref}$  are used ( $SWETR = 1$ ) or basic data on solar radiation, air temperature, air humidity and wind speed. These basic weather data may be specified daily or with shorter, constant time intervals ( $SWMETDETAIL = 1$ ). In case of daily meteorological weather records, SWAP may distribute the evapotranspiration fluxes uniform over the day (default) or sinusoidal during daylight ( $SWETSINE = 1$ ). As listed in Box 3.1, the rainfall input may range from daily amounts to short time rainfall amounts.

As described in Par. 3.4, the partitioning of potential transpiration and evaporation fluxes can be based on crop and soil factors, or on direct application of the Penman-Monteith equation. With the switch  $SWDIVIDE$  the user selects the preferred method. For many applications daily input of solar radiation, air temperature, air humidity and wind speed is preferred. In that case SWAP may apply the

Penman-Monteith method to determine  $ET_p$ . If some of these data are missing or unreliable, alternative methods to determine  $ET_{ref}$  in combination with crop factors are advised.

Input of daily rainfall amounts will suffice for most applications. However when surface runoff is expected, daily rainfall amounts may underestimate the amount of surface runoff. To calculate surface runoff, actual rainfall intensities should be used.

### 3.7.2 Weather data

In case of daily weather records, the data should be specified as listed in Box 3.2. Missing data are given the number -99.9. When SWAP should use Penman Monteith (SWETR = 0, Box 3.1), data on solar radiation, air temperature (min and max), air humidity and wind speed are required. When SWAP should simulate detailed crop growth (Chapter 7), data on solar radiation and air temperature (min and max) are required. For rainfall, either daily amounts (SWRAIN = 0, Box 3.1) or daily amounts plus duration (SWRAIN = 2, Box 3.1) should be specified.

```

Box 3.2 Daily basic weather data.

```

Alternatively weather records can be specified with short, constant time intervals (> 15 minutes) according to the format listed in Box 3.3. Radiation and rainfall denote total amounts during the time interval. Air temperature, humidity and wind speed denote average values during the time interval.

A third combination is daily evapotranspiration data and detailed rainfall data. In this case evapotranspiration data are input according to Box 3.2, while the rainfall data are input according to Box 3.4. The rainfall data follow the format of a tipping bucket measurement device: the rainfall amount corresponds to the total amount in the previous period.

### 3.7.3 Soil data

Box 3.5 lists the soil data which are required to determine the actual evaporation at the soil surface. The soil factor CFBS can be used to transform reference crop evapotranspiration into potential soil evaporation (see Section 3.3.2 and Table 3.2). Commonly a soil factor CFBS = 0.5 is used.

Three options are offered to reduce soil evaporation according to the maximum water flux which can be delivered by the soil. Applying straight soil physical theory, the maximum soil water flux according to Darcy would suffice. However, as discussed in Section 3.6, this method in general overestimates actual soil evaporation. Therefore we recommend to use in addition to the Darcy flux, reduction with either the Black or Boesten/Stroosnijder method (SWREDU = 1 or 2).

Default soil evaporation coefficient for Black equals  $0.35 \text{ cm d}^{-0.5}$ , and for Boesten/Stroosnijder  $0.54 \text{ cm}^{-0.5}$ .

### Box 3.5 Soil data to derive actual soil evaporation in main file \*.SWP.

### 3.7.4 Plant data

The required plant input data to calculate evapotranspiration and rainfall interception will be listed at the end of Chapter 7. The theory in this chapter and the description in the input file should be sufficient to provide the proper input values for most variables. In this section we provide more information on the input for the detailed oxygen module (Par. 3.5.3). This module calculates the root uptake reduction factor  $a_{rw}$  as function of plant characteristics and plant physiological processes, rooting depth, gas filled porosity, soil temperature, soil physical properties and soil microbial activity.

Most input parameters required for the oxygen module (Table 3.3) are already standard input to SWAP simulations. When SWAP is used with the simple, static crop module, crop development is input and plant physiological processes are not simulated. Consequently, for the simulation of oxygen stress some additional crop parameters are required of i) characteristics of the plant roots to simulate the root oxygen demand and ii) soil characteristics to simulate the oxygen consumption by soil microbial activity (Table 3.3, column 'Stat'). Using dynamic crop development decreases the number of extra input parameters from nine to four (Table 3.3, column 'Dyn').

Using dynamic crop development (WOFOST) allows to describe the plant physiological processes, that determine the oxygen demand of plant roots, in more detail than with the static crop module. The following variables are relevant:

- rooting depth
- root biomass
- ratio total root respiration : maintenance respiration

WOFOST simulates rooting depth and root biomass dynamically (daily). Root biomass is used to simulate the root maintenance respiration. The oxygen module calculates total root respiration from the maintenance respiration by multiplication with a factor  $\eta$ : the ratio of total respiration and maintenance respiration (Bartholomeus et al., 2008). The factor  $\eta$  is derived on a daily basis from root growth respiration and maintenance respiration as simulated with WOFOST. For simulations with the simple crop module,  $\eta$  is an input variable.

It should be noted that WOFOST uses air temperature to simulate the temperature dependence of the plants' maintenance respiration. This also holds for the simulation of root respiration. Within the oxygen module however, maintenance respiration is simulated with soil temperature as input.

It is optional to either calculate or simulate the root radius (Table 3.3, SwRootRadius). The latter option requires four extra input parameters.

Table 3.4 provides oxygen stress parameter values for a static grass crop; Table 3.5 provides parameter values for dynamic crop growth simulation (WOFOST, see Chapter 7) for the crops grass, potato and maize.

**Table 3.3** Overview of input parameters required for the simulation of oxygen stress for both a static (Stat) and dynamic (Dyn) crop. X indicates if a parameter is input to Stat and/or Dyn.

Name and requirements in crop input file (*.crp)		Options (input is required when conditions are valid)

## 4 Surface runoff, interflow and drainage

The interaction between soil water and surface water is of importance in lowland areas. Dependent on the specific setting in the landscape of the field studied, different types of pathways and interconnections may play a role.

Surface runoff that occurs when the rainfall rate exceeds the infiltration rate is called *Horton overland flow*. A second form of runoff occurs after the water storage volume of a soil has been exceeded, which means that the groundwater table has reached the soil surface. This runoff is commonly called the *Dunne overland flow*. It occurs in areas with a shallow groundwater table and moderate rainfall of long duration.

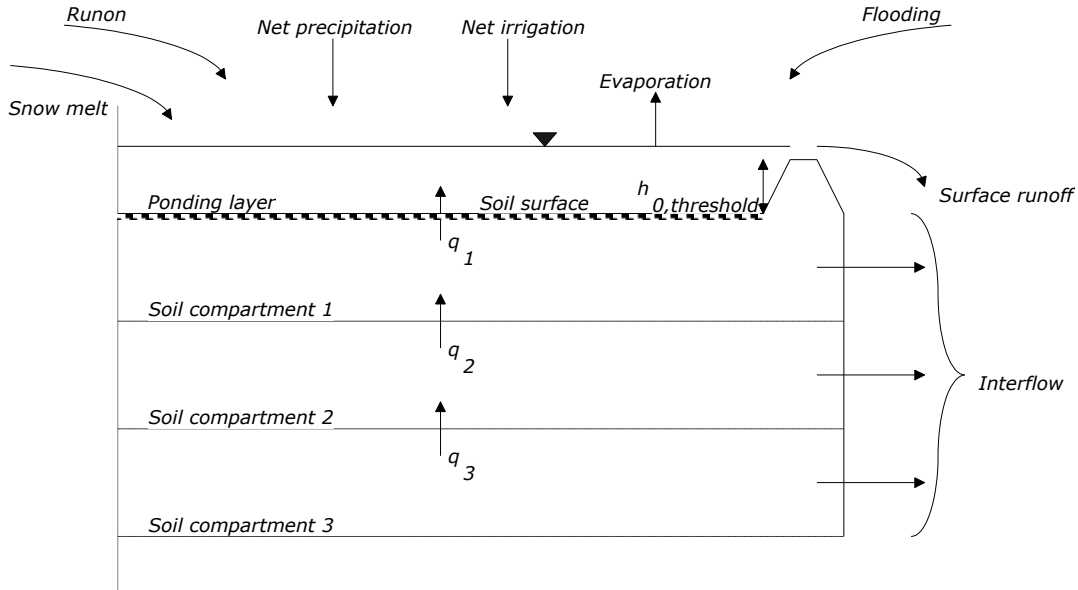

Interflow can be defined as the near-surface flow of water within the soil profile resulting in seepage to a stream channel within the time frame of a storm hydrograph. Interflow involves both unsaturated and saturated flows, the latter being in zones of limited vertical extent caused by soil horizons impeding vertical percolation. The mechanisms by which subsurface flow enters streams quickly enough to contribute to streamflow responses to individual rainstorms are summarized in various publications (Beven 1989).

Infiltration excess moves slowly downwards and once it has reached the saturated zone, it is called ground water. Ground water moves downward and laterally through the subsurface and eventually discharges through tile drains, field ditches or other open conduits. A tile drain is a perforated conduit, such as tile, pipe or tubing, installed below the ground surface to intercept and convey drainage water.

The SWAP model can take account for the different types of interconnections between soil moisture/groundwater and surface water by offering options for describing surface runoff as a non-linear function of water storage on the field, interflow as a non-linear function of the groundwater elevation when it has reached the near-surface zone and the discharge to a series of drainage systems. Options to simulate dynamically the levels in surface water systems provide the possibility to describe the feedback and the close interconnection between groundwater and surface water in stream valleys and polders.

## 4.1 Surface runoff

Surface runoff is one of the terms in the water balance of the ponding reservoir. The ponding reservoir stores a certain amount of excess water on top of the soil surface (Fig.4.1).

**Figure 4.1** Schematic representation of the near surface flux to a surface water system and the water balance of the ponding layer.

The water balance of the ponding reservoir is governed by:

$$\frac{\Delta h_0}{\Delta t} = q_{prec} + q_{irri} + q_{melt} + q_{runon} + q_{inun} + q_1 - q_{e,pond} - q_{runoff} - I_{ru} \quad (4.1)$$

Where  $\Delta h_0$  is the storage change of the ponding reservoir ( $\text{cm d}^{-1}$ ),  $q_{prec}$  is the precipitation flux subtracted with interception, ( $\text{cm d}^{-1}$ ),  $q_{irri}$  is the irrigation flux subtracted with interception ( $\text{cm d}^{-1}$ ),  $q_1$  is the flux from the first model compartment to the ponding layer ( $\text{cm d}^{-1}$ ),  $q_{melt}$  is snowmelt ( $\text{cm d}^{-1}$ ),  $q_{runon}$  is the runon flux of water which enters the field from an upstream adjacent field ( $\text{cm d}^{-1}$ ),  $q_{inun}$  is the inundation or flooding from surface water to the field ( $\text{cm d}^{-1}$ ),  $q_{runoff}$  is surface runoff flux ( $\text{cm d}^{-1}$ ) and  $q_{e,pond}$  is the evaporation flux of the open water stored on the soil surface ( $\text{cm d}^{-1}$ ) and  $I_{ru}$  is the runoff into the macropores ( $\text{cm d}^{-1}$ , see Section 6.1.2)

Surface runoff occurs when the water storage in the ponding layer exceeds the critical depth of  $h_{0,threshold}$  (cm):

$$q_{runoff} = \frac{1}{\gamma} \left( \max(0, (h_0 - h_{0,threshold})) \right)^\beta \quad (4.2)$$

where  $h_0$  is the ponding depth of water (cm) on the soil surface,  $\gamma$  is a resistance parameter ( $\text{cm}^{\beta-1} \text{d}$ ) and  $\beta$  is an exponent (-) in the empirical relation. Inundation of the field from an adjacent water course can be simulated when the surface water level exceeds both  $h_0$  and  $h_{0,threshold}$ . This option is only available when the so-called extended drainage option is chosen (see Chapter 5).

## 4.2 Interflow

In some applications one may wish to describe an interflow system, which has a rapid discharge with short residence times of the water in the soil system. If the groundwater level  $\phi_{\text{gwI}}$  is higher than the hydraulic head of the drain  $\phi_{\text{drain},n}$ , the interflow flux is optionally calculated as:

$$q_{\text{drain},n} = \frac{\phi_{\text{gwI}} - \phi_{\text{drain},n}}{\max(\gamma_{\text{min}}, 1 \cdot \phi_{\text{gwI}} - \gamma_{\text{ref}})} \quad (4.3)$$

or as:

$$q_{\text{drain},n} = A_{\text{interflow}} (\phi_{\text{gwI}} - \phi_{\text{drain},n})^{B_{\text{interflow}}} \quad (4.4)$$

where  $q_{\text{drain},n}$  is the interflow flux ( $\text{cm d}^{-1}$ ),  $\gamma_{\text{min}}$  and  $\gamma_{\text{ref}}$  are the minimum and the reference resistance related to the interflow process, '1' is a factor that expresses the unit conversion and is equal to one ( $\text{d cm}^{-1}$ ) in this case.  $A_{\text{interflow}}$  is a conductance parameter ( $\text{cm}^{1-B} \text{d}^{-1}$ ) and  $B_{\text{interflow}}$  is an exponent (-) in the empirical relation. The subscript  $n$  points to the rule that in the SWAP model interflow is always assigned to the highest order of distinguished drainage systems.

## 4.3 Drain discharge

Although the entity for which the SWAP model operates is at field scale, the model is used both for field studies and for regional studies. The different spatial scales of operation are expressed among other things by the type of drainage relation and its associated parameters chosen. For the purpose of a drainage system at field scale, one may use one of the classical drainage equations, but for simulation of water discharge in the spatial entity of a sub-catchment, the use of a multiple drainage system formulation is more convenient. Table 4.1 provides a brief overview of the drainage options available in the SWAP model. Additionally, options are available to take account for the influence of surface water management strategies on soil water flow and drain discharge. The background and the implementation of this option is presented in Chapter 5.

**Table 4.1** Options to simulate drain discharge at field scale and at regional scale.

Scale of application	No of systems	Drainage flux relation	Drainage level
Field	Single drainage system	Hooghoudt or Ernst equation	Specified in model input
		Tabulated input	Implicitly included in tabulated input
Regional	Single drainage system	Tabulated input	Implicitly included in tabulated input
	Multiple drainage system	Drainage resistance per sub-system	Specified in model input per drainage system
		Drainage resistance per sub-system dependent on wetted perimeter of drains	Specified in model input per drainage system
			Simulated (see Chapter 5)

The options provided by the SWAP model are limited to lowland conditions. Subsurface groundwater flow and drainage response of sloping fields can better be described by 2D or 3D models or Boussinesq-equation based models. Another limitation of the drainage equations involves the steady-state assumption. Hysteresis phenomena in the groundwater – discharge relation as they can be observed in experimental data are attributed to the different possible shapes of the groundwater elevation surface pertaining to one groundwater level value. Although there are possibilities to conceptualize the 2D groundwater depth discharge relation for nonsteady-state conditions (Kraijenhoff van de Leur, 1957, Wesseling and Wesseling, 1984), such relation is not implemented. These relations consider only one over-all value for the storage coefficient and neglect the influence of the pressure

head variations in space and time on the storativity. If such phenomena are of interest for drainage flow simulations, the reader is referred to 2D and 3D models as MODFLOW-VSF (Thoms et al., 2006), SUTRA (Voss and Provost, 2002), FEMWATER (Lin et al., 1997), and HYDRUS (Šimůnek et al., 2007).

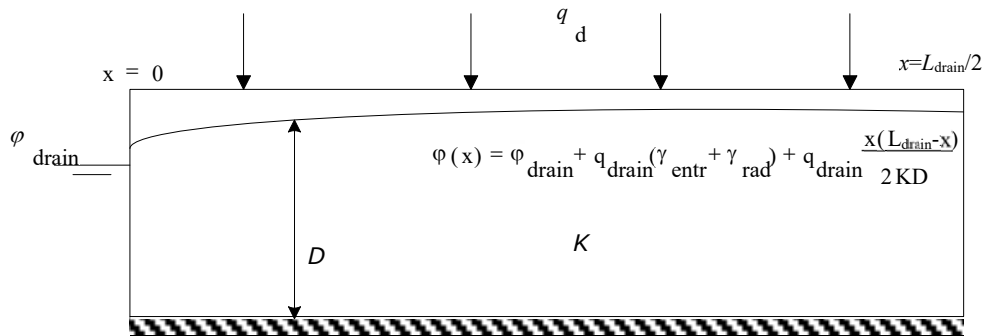

The drainage flux are incorporated in the numerical solution to the Richards equation (see Chapter 2) by specifying it as a sink term. The drainage relations presented in Section 4.3 are conceptualizations of 2D and 3D saturated groundwater flow to surface water systems and are based on the head difference between groundwater elevation and drainage level. Assignment of drainage sink term values in the Richards equation involves a conceptualization of the 2D and 3D flow field, which is briefly explained in Par. 4.4. Optionally, to provide possibilities to compare the SWAP model with other 1D soil moisture models as HYDRUS1D (Šimůnek et al., 1998), the drain flux can be described as a vertical flow in the model, which leaves the flow domain at the bottom.

It should be noticed that the calculation of drainage resistance should be attuned to the definition of the groundwater elevation as one of the driving forces of groundwater discharge and to the lower boundary condition one wants to impose. The general formulation of the drainage equation:

$$q_{\text{drain}} = \frac{(\phi_{\text{gwI}} \text{ or } \phi_{\text{avg}}) - \phi_{\text{drain}}}{\gamma_{\text{drain}}} \quad (4.5)$$

where  $\phi_{\text{gwI}}$  is the phreatic groundwater level midway between the drains or ditches (cm),  $\phi_{\text{avg}}$  is the averaged phreatic groundwater level midway between the drains or ditches (cm),  $\phi_{\text{drain}}$  is the drainage level (cm) and  $\gamma_{\text{drain}}$  is the drainage resistance (d).

Drainage relations are generally derived from the groundwater elevation as a function of distance. An example is given in Figure 4.2.

**Figure 4.2** Groundwater elevation as a function of distance as the basis for drainage equations.

For drainage design purposes, one may be interested in the maximum groundwater elevation ( $\phi_{\text{gwI}}$ ), but for the analysis of regional water management, the average groundwater elevation ( $\phi_{\text{avg}}$ ) is often a key variable to be studied. The different backgrounds reveals itself in the manner the drainage flux is calculated. For field applications, the relation between the drainage flux and the groundwater elevation can be expressed by the Ernst equation, modified with respect to the introduction of an additional entrance resistance :

$$\phi_{\text{gwI}} = \phi_{\text{drain}} + q_{\text{drain}} \left( \gamma_{\text{entr}} + \gamma_{\text{rad}} + \frac{L_{\text{drain}}^2}{8KD} \right) \rightarrow q_{\text{drain}} = \frac{\phi_{\text{gwI}} - \phi_{\text{drain}}}{\gamma_{\text{entr}} + \gamma_{\text{rad}} + \frac{L_{\text{drain}}^2}{8KD}} \quad (4.6)$$

and for regional applications:

$$\phi_{\text{avg}} = \phi_{\text{drain}} + q_{\text{drain}} \left( \gamma_{\text{entr}} + \gamma_{\text{rad}} + \frac{L_{\text{drain}}^2}{12KD} \right) \rightarrow q_{\text{drain}} = \frac{\phi_{\text{avg}} - \phi_{\text{drain}}}{\gamma_{\text{entr}} + \gamma_{\text{rad}} + \frac{L_{\text{drain}}^2}{12KD}} \quad (4.7)$$

By comparing Eq. (4.6) with Eq. (4.7) it can be seen that the two definitions of  $\gamma_{\text{drain}}$  in the equations differ by the so-called shape factor. The shape factor  $\alpha$  is the ratio between the mean and the maximum groundwater level elevation above the drainage base:

$$\alpha = \frac{\phi_{\text{avg}} - \phi_{\text{drain}}}{\phi_{\text{gwl}} - \phi_{\text{drain}}} \quad (4.8)$$

The shape factor depends on the vertical, horizontal, radial and entrance resistances of the drainage system (Ernst, 1978). For regional situations, where the 'horizontal' resistance to flow plays an important role, the shape factor is relatively small ( $\approx 0.7$ ). The smaller the horizontal resistance becomes, the more 'rectangular' shaped the water table: in the most extreme case with all the resistance concentrated in the direct vicinity of the channel, the water table is level, except for the abrupt decrease towards the drainage base. In that case the shape factor approaches to unity.

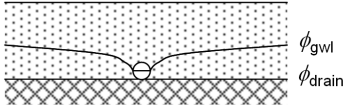

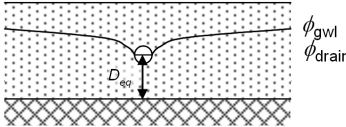

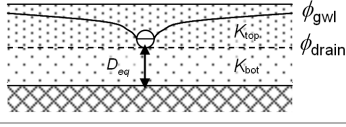

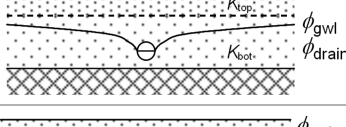

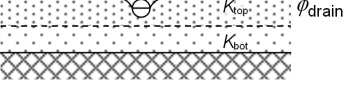

It should be noted that the parameters chosen to describe the relation between discharge and groundwater elevation should be attuned to the hydrological schematization. The combination of a Cauchy condition for the bottom boundary with a drainage relation for the lateral boundary may require an other formula (De Lange, 1999) than the one usually applied for drainage combined with a flux bottom boundary condition. Also the coupling of the SWAP model to a regional groundwater model by exchanging information concerning fluxes and hydraulic heads at the bottom of the schematization may require alternative formulations for the drainage equation to be used.

The influence of frost at a certain depth can optionally be accounted for by the reduction of prevailing drainage fluxes at that depth similar to the reduction of hydraulic conductivities (see Chapter 2).

#### 4.3.1 Field scale drainage relation according to Hooghoudt and Ernst

The drainage equations of Hooghoudt and Ernst allow the evaluation of drainage design and are based on the drainage flux as a function of the head difference the maximum groundwater elevation midway between the drains and the drainage level. Depending on position of the groundwater level, the drainage level and the possibility for water supply in the surface water system, the channels will act as either drainage or sub-irrigation media. The theory behind the field drainage equations used for drainage design purposes is summarized by Ritzema (1994). Five typical drainage situations are distinguished (Table 4.2). For each of these situations the drainage resistance  $\gamma_{\text{drain}}$  (d) can be defined.

**Table 4.2** Five field drainage situations considered in SWAP (after Ritzema, 1994).

Case	Schematization	Soil profile	Drain position	Theory
1		Homogeneous	On top of impervious layer	Hooghoudt, Donnan
2		Homogeneous	Above impervious layer	Hooghoudt with equivalent depth
3		Two layers	At interface of two soil layers	Hooghoudt
4		Two layers ( $K_{top} \ll K_{bot}$ )	In bottom layer	Ernst
5		Two layers ( $K_{top} \gg K_{bot}$ )	In top layer	Ernst

### Case 1: Homogeneous profile, drain on top of impervious layer

The drainage resistance is calculated as:

$$\gamma_{\text{drain}} = \frac{L_{\text{drain}}^2}{4K_{\text{hprof}}(\phi_{\text{gwl}} - \phi_{\text{drain}})} + \gamma_{\text{entr}} \quad (4.9)$$

with  $K_{\text{hprof}}$  the horizontal saturated hydraulic conductivity above the drainage basis ( $\text{cm d}^{-1}$ ),  $L_{\text{drain}}$  the drain spacing (cm) and  $\gamma_{\text{entr}}$  the entrance resistance into the drains and/or ditches (d). The value for  $\gamma_{\text{entr}}$  can be obtained, analogous to the resistance value of an aquitard, by dividing the 'thickness' of the channel walls with the permeability. If this permeability does not differ substantially from the conductivity in the surrounding subsoil, the numerical value of the entry resistance will become relatively minor.

### Case 2: Homogeneous profile, drain above impervious layer

This drainage situation has been originally described by Hooghoudt (1940). An extension for the entrance resistance has been added later on. The drainage resistance follows from:

$$\gamma_{\text{drain}} = \frac{L_{\text{drain}}^2}{8K_{\text{hprof}}D_{\text{eq}} + 4K_{\text{hprof}}(\phi_{\text{gwl}} - \phi_{\text{drain}})} + \gamma_{\text{entr}} \quad (4.10)$$

where  $D_{\text{eq}}$  is the equivalent depth (cm) that accounts for the extra head loss near the drains caused by converging flow lines (Hooghoudt, 1940). The numerical solution of Van der Molen and Wesseling (1991) is employed to obtain an estimate for  $D_{\text{eq}}$ . A characteristic dimensionless length scale  $x$  is used:

$$x = 2\pi \frac{\phi_{\text{drain}} - z_{\text{imp}}}{L_{\text{drain}}} \quad (4.11)$$

where  $z_{\text{imp}}$  is the level of the impervious layer. The equivalent depth  $D_{\text{eq}}$  is approximated for three ranges of  $x$  as:

$$\text{If } x < 10^{-6}: \quad D_{\text{eq}} = \phi_{\text{drain}} - z_{\text{imp}} \quad (4.12)$$

$$D_{eq} = \frac{L_{drain}}{\frac{8}{\pi} \ln \left( \frac{\phi_{drain} - z_{imp}}{\pi r_{drain}} \right) + \frac{L_{drain}}{\phi_{drain} - z_{imp}}} \quad (4.13)$$

If  $10^{-6} < x < 0.5$ :

$$D_{eq} = \frac{L_{drain}}{\frac{8}{\pi} \left( \ln \left( \frac{L_{drain}}{\pi r_{drain}} \right) + \sum_{k=1,3,5,\dots}^{\infty} \frac{4e^{-2kx}}{k(1-e^{-2kx})} \right)} \quad (4.14)$$

If  $x > 0.5$ :

### Case 3: Heterogeneous soil profile, drain at interface between both soil layers

The drainage resistance follows from:

$$\gamma_{drain} = \frac{L_{drain}^2}{8K_{hbot} D_{eq} + 4K_{htop} (\phi_{gwl} - \phi_{drain})} + \gamma_{entr} \quad (4.15)$$

with  $K_{htop}$  and  $K_{hbot}$  the horizontal saturated hydraulic conductivity ( $\text{cm d}^{-1}$ ) of upper and lower soil layer, respectively. The equivalent depth  $D_{eq}$  is calculated using Eq. (4.11) to Eq. (4.14).

### Case 4: Heterogeneous soil profile, drain in bottom layer

The drainage resistance is calculated according to Ernst (1956) with later extensions for the entrance resistance as:

$$\gamma_{drain} = \gamma_{ver} + \gamma_{hor} + \gamma_{rad} + \gamma_{entr} \quad (4.16)$$

where  $\gamma_{ver}$ ,  $\gamma_{hor}$ ,  $\gamma_{rad}$  and  $\gamma_{entr}$  are the vertical, horizontal, radial and entrance resistance ( $\text{d}^{-1}$ ), respectively. The vertical resistance is calculated by:

$$\gamma_{ver} = \frac{\phi_{gwl} - z_{int}}{K_{vtop}} + \frac{z_{int} - \phi_{drain}}{K_{vbot}} \quad (4.17)$$

with  $z_{int}$  the level of the transition (cm) between the upper and lower soil layer, and  $K_{vtop}$  and  $K_{vbot}$  the vertical saturated hydraulic conductivity ( $\text{cm d}^{-1}$ ) of the upper and lower soil layer, respectively. The horizontal resistance is calculated as:

$$\gamma_{hor} = \frac{L_{drain}^2}{8K_{hbot} D_{bot}} \quad (4.18)$$

with  $D_{bot}$  the depth of the contributing layer below the drain level (cm), which is calculated as the minimum of  $(\phi_{drain} - z_{imp})$  and  $\frac{1}{4} L_{drain}$ . The radial resistance is calculated using:

$$\gamma_{rad} = \frac{L_{drain}}{\pi \sqrt{K_{hbot} K_{vbot}}} \ln \left( \frac{D_{bot}}{u_{drain}} \right) \quad (4.19)$$

with  $u_{drain}$  the wet perimeter (cm) of the drain.

### Case 5: Heterogeneous soil profile, drain in top layer

Again the approach of Ernst (1956), with later extensions for the entrance resistance, is applied. The resistances are calculated as:

$$\gamma_{ver} = \frac{\phi_{gwl} - \phi_{drain}}{K_{vtop}} \quad (4.20)$$

$$\gamma_{hor} = \frac{L_{drain}^2}{8K_{htop} D_{top} + 8K_{hbot} D_{bot}} \quad (4.21)$$

$$\gamma_{rad} = \frac{L_{drain}}{\pi \sqrt{K_{hbot} K_{vbot}}} \ln \left( g_{drain} \frac{\phi_{drain} - z_{int}}{u_{drain}} \right) \quad (4.22)$$

with  $D_{top}$  equal to  $(\phi_{drain} - z_{int})$  and  $g_{drain}$  is the drain geometry factor, to be specified in the input. The value of  $g_{drain}$  in Eq. (4.22) depends on the ratio of the hydraulic conductivity of the bottom ( $K_{hbot}$ ) and the top ( $K_{htop}$ ) layer. Ernst (1962) distinguished the following situations:

- $K_{hbot}/K_{htop} < 0.1$ : the bottom layer can be considered impervious and the case is reduced to a homogeneous soil profile and  $g_{drain} = 1$
- $0.1 < K_{hbot}/K_{htop} < 50$ :  $g_{drain}$  depends on the ratios  $K_{hbot}/K_{htop}$  and  $D_{bot}/D_{top}$ , as given in Table 4.3
- $K_{hbot}/K_{htop} > 50$ :  $g_{drain} = 4$

**Table 4.3** The geometry factor  $g_{drain}$  (-), as obtained by the relaxation method (after Ernst, 1962).

$K_{hbot}/K_{htop}$	$D_{bot}/D_{top}$						
	1	2	4	8	16	32	1
1	2.0	3.0	5.0	9.0	15.0	30.0	2.0
2	2.4	3.2	4.6	6.2	8.0	10.0	2.4
3	2.6	3.3	4.5	5.5	6.8	8.0	2.6
5	2.8	3.5	4.4	4.8	5.6	6.2	2.8
10	3.2	3.6	4.2	4.5	4.8	5.0	3.2
20	3.6	3.7	4.0	4.2	4.4	4.6	3.6
50	3.8	4.0	4.0	4.0	4.2	4.6	3.8

#### 4.3.2 Field scale drainage relation defined by a tabulated function

The SWAP model provides an option to specify a tabulated drainage flux relationship as a function of the groundwater level. When this option is chosen, one should specify a number of  $(\phi_{gwl}, q_{drain})$  data-pairs. For a linear relation only two data-pairs suffices, but a non-linear relation requires more data-pairs. A non-linear relation can be either the result of:

- describing the drainage flux by the Hooghoudt equation;
- an analysis of the flux relation in a stratified profile by means of a numerical model
- an analysis of measured field data.

The general shape of such a relation is given in Figure 4.3. Specifying a non-linear relation by means of a tabulated function involves a linearization, since flux values are derived by linear interpolation. Specifying more data pairs can reduce the inaccuracy which results from this type of linearization.

**Figure 4.3** Linearization of a non-linear drainage flux relation.

### 4.3.3 General aspects of regional scale drainage

#### Schematization

The groundwater-surface water system is described at the scale of a horizontal sub-region. A network of drainage devices consists of a hierarchical system of different order and incision depth, but only a single representative groundwater level is simulated for a sub-region, which is 'stretched' over a scale that in reality involves a variety of groundwater levels. In the following, due consideration will be given to the schematization of the surface water system, the simulation of drainage/sub-irrigation fluxes, and the handling of an open surface water level.

The regional surface water system consists of a hierarchical system of different order drainage devices (Figure 4.4), each with its own bed level, bed width, side-slope, and spacing conveyance capacity. The drainage devices can be connected to each other in different ways. In the man-made the ditches of the network systems act as perennial streams, connected to larger canals with a nearly equal surface water level. In the alluvial sandy areas of the Netherlands, the smaller streams may have intermittent character which only discharge water in periods with rainwater excess.

It should be noted that contrary to the classification notation used in geomorphological sciences, in this report the stream and canal order is dictated by the level of the stream bed or water level (drainage level) compared to the land surface level: the deeper the drainage level, the lower classification index.

The representative distance between drain devices  $L_{\text{drain},i}$  (m) is derived by dividing the area of the subregion  $A_{\text{reg}}$  ( $\text{m}^2$ ) by the total length of the  $i^{\text{th}}$  order channels,  $l_{\text{drain},i}$  (m):

$$L_{\text{drain},i} = \frac{A_{\text{reg}}}{l_{\text{drain},i}} \quad (4.23)$$

**Figure 4.4** Schematization of surface water system in a control unit.

In the surface water model, we assume that the different channels orders are connected in a dendritic manner. Together they form a surface water 'control unit' with a single outlet (indicated by the weir in Figure 4.4) and, if present, a single inlet. The surface water level at the outlet is assumed to be omnipresent in the subregion. Friction losses are neglected and thus the slope of the surface water level is assumed to be zero. This means that in all parts of the subregion the surface water level has the same depth below soil surface.

In the so-called 'multi-level' drainage or sub-irrigation approach employed by the SWAP model, it is possible that more than one type of surface water channel become active simultaneously. In the following, we will refer to channels in terms of their 'order' if their role as part of the surface water system is being considered. When considering their drainage characteristics we will refer to them in terms of their 'level'.

The SWAP model has the option for specifying resistances for calculating the sub-irrigation flux that differ from the resistance values used for drainage. An additional model option involves the limitation of the sub-irrigation rate by defining the groundwater level  $\phi_{\text{avg}}^{\text{min}}$  at which the maximum sub-irrigation

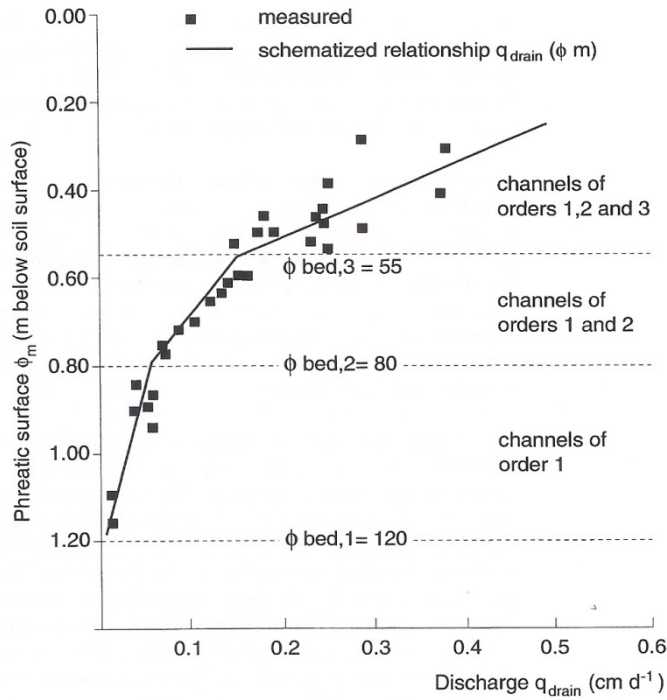

rate is reached. Such a limitation is needed because the sub-irrigation rate does not increase infinitely when the groundwater level lowers.

**Figure 4.5** Linear relationships between drainage ( $q_{\text{drain}} > 0$ ) and infiltration ( $q_{\text{drain}} < 0$ ) flux and mean groundwater level  $\phi_{\text{avg}}$ .

#### 4.3.4 Regional scale drainage relation defined by a tabulated function

An example of a non-linear relation between discharge and groundwater elevation resulting from an analysis of observed field data is presented in Figure 4.6 (Massop and De Wit, 1994). It can be seen from this figure that the non-linear relation may be linearized to a piece-wise linear relation in which each part of this relation corresponds to a certain type of drainage system. From Figure 4.6 one can infer that the drainage base of the larger channels is roughly at  $z = -120$  cm, as no discharges were measured below that level. The schematized  $q_{\text{drain}}(\phi_{\text{avg}})$ -relationship has transition points at mean groundwater levels of 80 and 55 cm below soil surface. These transition points correspond to the 'representative' bed levels of the second and third order channels. These levels could be imposed to the SWAP model as drainage levels.

**Figure 4.6** Discharge  $q_{\text{drain}}$  as function of mean phreatic surface  $\phi_{\text{avg}}$  in the Beltrum area (Massop and de Wit, 1994).

#### 4.3.5 Multi-level drainage with fixed resistances and imposed drainage levels

Prior to any calculation of the drainage/sub-irrigation rate, we determine whether the flow situation involves drainage, sub-irrigation, or neither. No drainage or sub-irrigation will occur if both the groundwater level and surface water level are below the drainage base.

Drainage will only occur if the following two conditions are met:

- the groundwater level is higher than the channel bed level;
- the groundwater level is higher than the surface water level.

Sub-irrigation can only occur if the following two conditions are met:

- the surface water level is higher than the channel bed level;
- the surface water level is higher than the groundwater level.

In both cases we take for the drainage base,  $\phi_{\text{drain}}$  (cm), either the surface water level,  $\phi_{\text{sur}}$  (cm), or the channel bed level,  $z_{\text{bed}}$  (cm), whichever is higher:

$$\phi_{\text{drain}} = \max(\phi_{\text{sur}}, z_{\text{bed}}) \quad (4.24)$$

The hydraulic head  $\phi$  is defined positive upward, with zero at the soil surface.

The drainage/infiltration flux  $q_{\text{drain},i}$  ( $\text{cm d}^{-1}$ ) to/from each surface water system  $i$  is calculated from the linear relation:

$$q_{\text{drain},i} = \frac{\phi_{\text{avg}} - \phi_{\text{drain},i}}{\gamma_{\text{drain},i}} \quad (4.25)$$

where  $\phi_{\text{drain},i}$  is the drainage base is equal to the surface water level of system  $i$  (cm below the soil surface) and  $\gamma_{\text{drain},i}$  is the drainage resistance of system  $i$  (d). Similar to the case of single-level drainage, a drainage level is only 'active' if either the groundwater level or the surface water level is higher than the channel bed level. The drainage base is determined separately for each of the

drainage levels. In computing the total flux  $q_{drain}^{tot}$  to/from surface water, the contributions of the different channel orders are simply added:

$$q_{drain}^{tot} = \sum_{i=1}^n q_{drain,i} \quad (4.26)$$

#### 4.3.6 Multi-level drainage with surface water dependent resistances and simulated drainage levels

In most applications, the control unit involves the primary watercourse; the largest canals with the deepest channels beds. An option is available to specify that the primary watercourse, e.g., a large river, functions separately from the other watercourses within the sub-regional surface water system. In that case the primary water courses have their own surface water level which should be specified in the input. In the real situation there may be some interaction between the primary water course and the control unit: for instance a pumping station for removal of drainage water, and/or an inlet for letting in external surface water supply (Figure 4.4). The hydraulics of such structures are not included in the model. Conveyance processes within the surface water devices are not described.

Contrary to the model option described in Par 4.3.5, the influence of the surface water level on drainage resistances can be accounted for by distinguishing two parts of the resistance: 1) a part independent of the surface water level and 2) a part that is adjusted by the level. For the drainage case:

$$\gamma_{drain,i} = \gamma_{drain,i}^0 + \gamma_{entr,i}^* \frac{L_{drain,i}}{u_{drain,i}} \quad (4.27)$$

And for the sub-infiltration case:

$$\gamma_{infil,i} = \gamma_{infil,i}^0 + \gamma_{exit,i}^* \frac{L_{drain,i}}{u_{drain,i}} \quad (4.28)$$

where  $\gamma_{drain,i}^0$  and  $\gamma_{infil,i}^0$  are the level independent parts of the drainage and infiltration resistance and resp.  $\gamma_{entr,i}^*$  and  $\gamma_{exit,i}^*$  are the entrance and exit resistance factor per unit drain distance ( $L_{drain,i}$ ) and divided by the wetted perimeter ( $u_{drain,i}$ ). The radial resistance has been lumped with the entrance or exit resistance. By assuming a trapezoidal cross section of the water courses, the wetted perimeter can be calculated as:

$$u_{drain,i} = w_{bed,i} + \max \left( 0, 2 \cdot (\varphi_{sur} - z_{bed,i}) \sqrt{1 + \frac{1}{\alpha_{sl,i}^2}} \right) \quad (4.29)$$

where  $w_{bed,i}$  is the channel bed width (cm) and  $\alpha_{sl,i}$  (-) is the slope of the channel bank.

Another feature of this model option includes the ability to simulate the flooding of the field when the surface water level higher appears to be higher than both the ponding sill and the ponding level or groundwater level (Figure 4.7).

**Figure 4.7** In-between position of groundwater/ponding level  $h_0$  and surface waterlevel  $\phi_{sur}$  in case of surface runoff (left) and flooding (right).

The model concept for flooding does not take account for the resistance of water flowing on the field surface and an immediate equilibrium between the ponding level and the surface water level is assumed when flooding occurs.

## 4.4 Distribution with depth of drainage fluxes

### 4.4.1 Implicit approach of travel times

In this section, the concept for the distribution drainage fluxes with depth as one of the sink terms in the SWAP model is described. Although the concept discussed here is valid for a region having any number of drainage levels, only three drainage systems are considered for reasons of convenience.

One-dimensional leaching models generally represent a vertical soil column. Within the unsaturated zone, solutes are transported by vertical water flows, whereas in the saturated zone the drainage discharge can have a three dimensional flow pattern. Van Ommen (1986) has shown that for a simple single-level drainage system, the travel time distribution is independent from the size and the shape of the recharge area. Under these assumptions, the average concentration in drainage water can mathematically be described by the linear behaviour of a single reservoir. But, the non-homogeneous distribution of exfiltration points, the variety of hydraulic properties and the influence of stratified soil chemical characteristics necessitates to distinguish between the different soil layers.

The distribution of drainage fluxes with depth is used to describe the travel time distribution of drainage water in an implicit manner. Drainage fluxes are treated as lateral sink terms of the water balance in the SWAP model. The vertical flux  $q_y$  in the saturated zone of the SWAP model relates to the distribution of lateral drainage rate sink terms according to:

$$\frac{dq_y}{dy} = -\frac{q_{\text{drain}}}{D} \quad (4.30)$$

where  $D$  is the depth of the zone for which  $q_{\text{drain}}$  has a certain value. Assume that a fluid particle is at the depth of  $y_0$  at time  $t_0$ . The time it takes for this particle to reach a depth  $y$  is given by:

$$t - t_0 = \int_{y_0}^y \frac{\varepsilon dy}{q_y(y)} \quad (4.31)$$

The travel time relation is governed by the vertical flux as a function of depth and the porosity. It can be seen from Eq. (4.30) that the vertical flux coheres with the drainage flux.

### 4.4.2 Discharge layers

The concept of the distribution of the drainage flux with depth for a single level drainage system can be very simple. The Dupuit-Forcheimer assumption involves disregarding the head loss due to radial flow and vertical flow in the largest part of the flow domain. Based on this rule, the groundwater movement towards drains in a non-stratified aquifer is considered as an uni-directional flow and the drainage flux is distributed uniformly with depth.

The distribution with depth for a multi-level drainage system should ideally be based on the 3-D flow paths of water parcels migrating to drains. But since such type of information is not available in the 1-D vertical model, additional assumptions have to be made. The concept of discharge layers has been introduced, representing the flow systems associated with each of the drains. Although the verification of the concept by comparing the depth of discharge layers with the streamline patterns generated by 2D models do not always agree, the concept enables the accounting of the different types of water courses and the stratification of hydraulic properties in the implicit travel time approach.

The discharge layers are considered as horizontal layers. Each layer occupies a certain part of the groundwater volume. The ratio between the occupied flow volumes  $V_i$  is derived from the proportionality between flow volumes and volumetric discharge rates:

$$\frac{V_i}{V_{i-1}} = \frac{Q_{\text{drain},i}}{Q_{\text{drain},i-1}} \quad (4.32)$$

The volumetric flux  $Q_{\text{drain},i}$  to drainage system  $i$ , is calculated as:

$$Q_{\text{drain},i} = L_{\text{drain},i} q_{\text{drain},i} \quad (4.33)$$

**Figure 4.8** Schematization of regional groundwater flow to drains of three different orders.

First order drains act also as field ditches and trenches and next higher drains act partly as third order drains. In the SWAP-model the lumped discharge flux per drainage system is computed from the relation between groundwater elevation and drainage resistance. Figure 4.8 shows the schematization of the regional groundwater flow, including the occupied flow volumes for the nested drain systems. The volume  $V_i$  consists of summed rectangles  $L_i D_i$  of superposed drains, where  $D_i$  is the thickness (cm) of discharge layer  $i$ .

The flow volume  $V_i$  assigned to drains of order 1, 2 and 3 is related to drain distances  $L_i$  and thickness  $D_i$  of discharge layers as follows:

$$V_1 = L_1 D_1 + L_2 D_2 + L_3 D_3 \quad (4.34)$$

$$V_2 = L_2 D_2 + L_3 D_3 \quad (4.35)$$

$$V_3 = L_3 D_3 \quad (4.36)$$

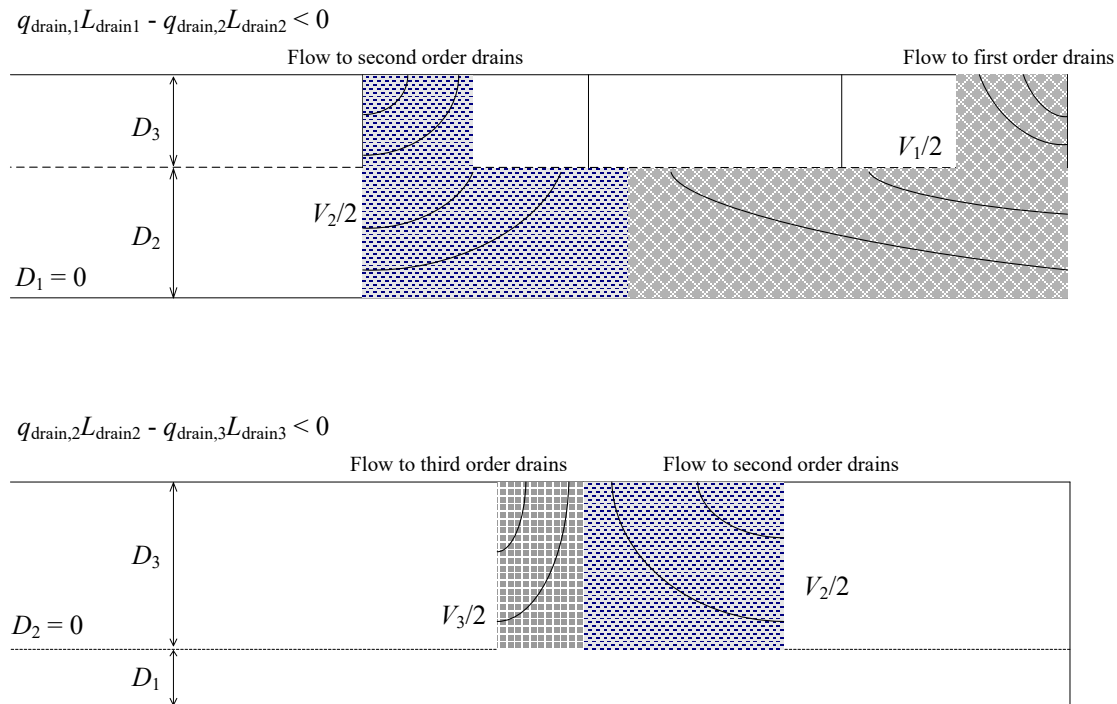

Rewriting Eq. (4.34) to (4.36) and substituting Eq. (4.32) and Eq. (4.33) yields an expression which relates the proportions of the discharge layer to the discharge flow rates:

$$L_1 D_1 : L_2 D_2 : L_3 D_3 = (q_{\text{drain},1} L_{\text{drain},1} - q_{\text{drain},2} L_{\text{drain},2}) : (q_{\text{drain},2} L_{\text{drain},2} - q_{\text{drain},3} L_{\text{drain},3}) : (q_{\text{drain},3} L_{\text{drain},3}) \quad (4.37)$$

In theory, the terms  $(q_{\text{drain},1} L_{\text{drain},1} - q_{\text{drain},2} L_{\text{drain},2})$  and  $(q_{\text{drain},2} L_{\text{drain},2} - q_{\text{drain},3} L_{\text{drain},3})$  can take negative values for specific combinations of  $q_{\text{drain},1} L_{\text{drain},1}$ ,  $q_{\text{drain},2} L_{\text{drain},2}$  and  $q_{\text{drain},3} L_{\text{drain},3}$ . When

$(q_{\text{drain},1} L_{\text{drain},1} - q_{\text{drain},2} L_{\text{drain},2}) < 0$  it is assumed that  $D_1$  will be zero and the nesting of superposed flows systems on top of the flow region assigned to drainage class 1 will not occur. Likewise, a separate nested flow region related to a drainage class will not show up when  $(q_{\text{drain},2} L_{\text{drain},2} - q_{\text{drain},3} L_{\text{drain},3}) < 0$ .

These cases are depicted schematically in Figure 4.9.

**Figure 4.9** Schematization of regional groundwater flow to drains of three orders when either  $q_{\text{drain},1} L_{\text{drain},1} - q_{\text{drain},2} L_{\text{drain},2} < 0$  or  $q_{\text{drain},2} L_{\text{drain},2} - q_{\text{drain},3} L_{\text{drain},3} < 0$ .

If the soil profile is stratified with respect to horizontal conductivities, the heterogeneity can be taken into account by substituting transmissivities  $KD$  for layer thicknesses in Eq. (4.37):

$$KD_1 : KD_2 : KD_3 = \frac{q_{\text{drain},1} L_{\text{drain},1} - q_{\text{drain},2} L_{\text{drain},2}}{L_{\text{drain},1}} : \frac{q_{\text{drain},2} L_{\text{drain},2} - q_{\text{drain},3} L_{\text{drain},3}}{L_{\text{drain},2}} : q_{\text{drain},3} \quad (4.38)$$

Lateral drainage fluxes to a certain drainage system per nodal point are calculated by multiplying the flux and the transmissivity proportion of that nodal point in the total transmissivity of the discharge layer.

In deep aquifers, the thickness of a model discharge layer is limited by:

$$D \leq \frac{L_{\text{drain}}}{4} \sqrt{\frac{K_v}{K_h}} \quad (4.39)$$

where  $K_v$  is the vertical conductivity and  $K_h$  is the horizontal conductivity. In stratified aquifers, the weighted arithmetic mean is used for the horizontal conductivity and the weighted harmonic mean is used for the vertical conductivity.

The top of any of the discharge layers is situated at the average groundwater level. This implies that solute transport to drains is calculated for the soil compartments between the simulated groundwater level and the bottom of the discharge layer. The groundwater level as the defined top of the zone that contributes to surface water loading may be inaccurate in case of concentration profiles with steep gradients. In reality the surface water load is determined by the present concentrations and water fluxes at the exfiltration zone in the drain. From Figure 4.10 (left) it can be seen that the concentrations at the drain bottom and at the depth of the surface water level are lower than the ones at the groundwater level. In such case the concept will lead to an over estimation to the surface water load relative to the results of 2D models. The SWAP model provides an option to specify the top of the zone that contributes to surface water loading as a function of the average groundwater level and the drainage level ( $z_{\text{top}}$ , Figure 4.10; right) according to:

$$z_{\text{top}} = f_{z_{\text{top}}} \varphi_{\text{avg}} + (1 - f_{z_{\text{top}}}) \varphi_{\text{drain}} \quad (4.40)$$

**Figure 4.10** 2D-schematization of the saturated flow domain with a hypothetical concentration profile indicated by gray shading (left) and the schematization of the top of the zone that contributes to surface water loading (right).

## 4.5 User instructions

### 4.5.1 Surface runoff

The maximum height of ponded water stored  $h_{0,\text{threshold}}$  on the field surface is determined by the irregularities and the slope of the soil surface. Also the extend to which local field depressions are connected to each other and are connected to the surface water affects the value of  $h_{0,\text{threshold}}$ . Typical values range from 0.5 to 2 cm for well maintained agricultural fields. Since it is impossible to measure the value of  $h_{0,\text{threshold}}$  directly, the value should be established by expert-judgement or model calibration. The value can be specified as a constant, or may fluctuate with time.

As surface runoff is a rapid process, the resistance  $\gamma$  will typically take values of less than 1 d. When the dynamics of surface runoff are relevant, the values of resistance  $\gamma$  (RSRO) and exponent  $\beta$  (RSROEXP) might be derived from experimental data or from a hydraulic model of soil surface flow.

### 4.5.2 Interflow

For describing the interflow process, a non-linear relation can be used. Such relation may useful for taking account for the horizontal flow in the saturated zone above drainage level may yield a non-linear relation contrary to relation based on the assumption made in the derivation of the horizontal resistance in the Ernst-equation. Another reason to introduce a non-linear relation for interflow may be the occurrence of hillslope. Sometimes it is possible to relate the parameters  $A_{interflow}$  and  $B_{interflow}$  to a specific flow concept, but most of the model user has to rely on expert judgement of model calibration.

```

The input requirements for the simulation of multi-level drainage given in Box 4.5 for a basic system with fixed resistances and imposed levels. In Box 4.6 the requirements are given for an extended system with surface water dependent resistances and simulated drainage levels.

Up to five different drainage levels can be specified. For each level the user can specify whether drainage or infiltration or both are allowed. Both the drainage and infiltration resistance needs to be specified by the user. In case of sub-irrigation, the entrance resistance (then denoted as  $\gamma_{inf}$ ) can be

---

either higher or lower than that for drainage ( $\gamma_{\text{drain}}$ ), depending on local conditions. A substantial raising of the surface water level can for instance result in infiltration through a more conductive 'bio-active' zone which will reduce the entrance resistance. In most situations with sub-irrigation the radial resistance will be higher than with drainage, because the wetted section of the subsoil is less than in the situation with drainage (the groundwater table becomes concave instead of convex). Especially if the conductivity is larger in the subsoil above the drainage base than in the deeper subsoil,  $\gamma_{\text{inf}}$  will be substantially higher than  $\gamma_{\text{drain}}$ . To deal with such cases, the model has the option for using sub-irrigation resistances that differ from the ones for drainage (e.g.  $\gamma_{\text{inf}} \approx 3/2 \gamma_{\text{drain}}$  in Figure 4.5).

When calibrating SWAP against measured groundwater levels it should be realised that SWAP calculates a field-average groundwater level. Measured groundwater levels represent a point of the convex or concave shaped groundwater table, depending on the position of the piezometer in the field in relation to the drains. Piezometers in the middle of two parallel drains will display stronger fluctuations of the groundwater level than the field-average level. Calibrating SWAP against these strong fluctuating groundwater levels will result in a calibrated model that deviates strongly from groundwater behavior at the field scale. To overcome this inaccuracy, it is advised to measure groundwater level movement in a row of piezometers perpendicular to the drain starting at a close (0.5 m) distance of the drain, including the drain level. From these measurements a shape-factor can be calculated that represents the relationship between the measured convex or concave groundwater table and the field average. This shape-factor can be used to convert measured levels into levels that are suitable for calibration of SWAP.

The input requirements to influence the distribution of drainage fluxes with depth are given in Box 4.7 and 4.8.

An implicit approach for travel times distribution (Section 4.4.1) requires specification of an anisotropy factor (COFANI) for each soil layer. This factor represents the division of horizontal over vertical saturated hydraulic conductivity and will generally increase with depth.

The exact location of the so-called discharge layers may be influenced by an adjustment of the upper boundary of the discharge layer (Box 4.8 and Section 4.4.2). This adjustment requires expert judgement and it is generally not recommended to apply/adjust it without thorough knowledge of the underlying processes.

# 5 Surface water management

## 5.1 Surface water balance

Surface water management options have been implemented in the SWAP model by taking account of the water balance of the surface water. The groundwater-surface water system is described at the scale of a horizontal subregion. The subregion has a single representative groundwater level and it is assumed that the soil profile occupies the whole surface area. This results in water balance terms of the soil profile that are computed per unit area ( $\text{cm}^3 \text{cm}^{-2}$ ) and have the *same numerical value for the sub-region as a whole*. The surface water system is simplified to a control unit for which the following surface water balance equation is formulated:

$$\frac{dV_{\text{sur}}}{dt} = q_{\text{sup}} - q_{\text{dis}} + q_{\text{drain}} + q_{\text{crackfl}} + q_{\text{runoff}} \quad (5.1)$$

where  $V_{\text{sur}}$  is the regional surface water storage ( $\text{cm}^3 \text{cm}^{-2}$ ),  $q_{\text{sup}}$  is external supply to the control unit ( $\text{cm}^3 \text{cm}^{-2} \text{d}^{-1}$ ),  $q_{\text{dis}}$  is discharge from control unit ( $\text{cm}^3 \text{cm}^{-2} \text{d}^{-1}$ ),  $q_{\text{drain}}$  is regional drainage flow ( $\text{cm}^3 \text{cm}^{-2} \text{d}^{-1}$ ),  $q_{\text{crackfl}}$  is bypass flow through cracks of a clay soil to drains or ditches ( $\text{cm}^3 \text{cm}^{-2} \text{d}^{-1}$ ), and  $q_{\text{runoff}}$  is either surface runoff or surface runoff ( $\text{cm}^3 \text{cm}^{-2} \text{d}^{-1}$ ).

The regional surface water storage  $V_{\text{sur}}$  ( $\text{cm}^3 \text{cm}^{-2}$ ) is the sum of the surface water storage in each order of the surface water system:

$$V_{\text{sur}} = \frac{1}{A_{\text{reg}}} \sum_{i=1}^n l_i A_{d,i} \quad (5.2)$$

in which  $A_{\text{reg}}$  is the total area of the sub-region ( $\text{cm}^2$ ),  $l_i$  the total length of channels/drains of order  $i$  in the sub-region (cm), and  $A_{d,i}$  is the wetted area of a channel vertical cross-section ( $\text{cm}^2$ ). The wetted area  $A_{d,i}$  is calculated from the surface water level  $\phi_{\text{sur}}$ , the channel bed level, the bottom width, and the side-slope. Substitution of Eq. (4.23) in Eq. (5.2) yields the expression:

$$V_{\text{sur}} = \sum_{i=1}^n \frac{A_{d,i}}{L_i} \quad (5.3)$$

Channels of order  $i$  only contribute to the storage if  $\phi_{\text{sur}} > z_{\text{bed},i}$ . The storage in tile drains is neglected. SWAP calculates the net discharge  $q_{\text{dis}} - q_{\text{sup}}$  for a given timestep and for specified surface water levels  $\phi_{\text{sur}}^j$  and  $\phi_{\text{sur}}^{j+1}$ :

$$q_{\text{dis}} - q_{\text{sup}} = \frac{V_{\text{sur}}^j(\phi_{\text{sur}}^j) - V_{\text{sur}}^{j+1}(\phi_{\text{sur}}^{j+1})}{\Delta t^j} + q_{\text{drain}} + q_{\text{crackfl}} + q_{\text{runoff}} \quad (5.4)$$

If the sum of the terms on the right hand side is positive, discharge has taken place and the supply is equal to zero. If the sum is negative, supply has taken place and the discharge is equal to zero.

The drainage flux is calculated by:

$$q_{\text{drain}} = \sum_{i=1}^n \frac{\phi_{\text{avg}} - \phi_{\text{drain},i}}{\gamma_{\text{drain},i}} \quad (5.5)$$

where the drainage level  $\phi_{\text{drain},i}$  is in this case equal to the channel bed level,  $z_{\text{bed},i}$ . When the groundwater level is situated above the highest bed level and with the surface water level is below the lowest one the total drainage flux. If the surface water level tends to rise to levels higher than the channel bed level  $z_{\text{bed},i}$ , the latter is replaced by the surface water level.

Calculation of the discharge rate  $q_{dis}$  is the last step in solving Eq. (5.4):

1. If the supply rate  $q_{sup}$  takes a positive value, the discharge is set to zero. The calculation of the supply rate is based on the comparison the target level and that actual surface water level. After establishing a target level it is examined whether the surface water level can take the target value. If necessary, surface water supply is used to attain the target level. The water supply should meet to the following criteria:
  - a. The supply rate should not exceed a user defined value of the maximum supply rate  $q_{sup,max}$
  - b. Water supply only occurs when the surface water level takes a value below the water supply level. This water supply level is defined as a tolerance value in relation to the target level.
2. For the fixed weir, the discharge follows from the iterative procedure to establish a target level from the stage – discharge relationship. This relationship can either be expressed in tabulated form or as a power function for “weir flow” (see Par 5.1.2.1).
3. For a soil moisture controlled weir, the discharge follows simply from the water balance equation as given by Eq. (5.4), with  $q_{sup}$  set to zero and the storage  $V_{sur}^{j+1}$  set equal to the storage for the target level. The discharge  $q_{dis}$  is then the only unknown left, and can be solved directly.

### 5.1.1 Multi-level drainage with imposed surface water levels

SWAP comprises an option for imposing a surface water level time series to be used as drainage level time series. When using this option it is assumed that the surface water level is equal for all drainage systems. Surface waters associated to the different drainage systems have open connections to each other and conduit resistances are neglected. This results to only one overall surface water level. The number of drainage systems to account for depends on the position of the groundwater level and the surface water level relative to the channel bed level.

### 5.1.2 Multi-level drainage with simulated surface water levels

Another option in the SWAP model is to simulate the surface water level on the basis of the control unit surface water balance. Then, the discharge is governed by a either a fixed weir or an automated weir. The user can specify different water management periods for which the settings of the weirs can be different. During each time step, SWAP determines in subsequent order:

1. the target level;
2. whether the target level is reached, and the amount of external supply that is needed (if any);
3. the discharge that takes place (if any) and the surface water level at the end of the time step.

Two options for describing the functioning of a weir are available: 1) the target level of a *fixed weir* coincides with the crest level, which has a constant value within a certain management period, or 2) the target level of *soil moisture controlled weir* is a function of a soil moisture state variable and is defined by a water management scheme.

#### 5.1.2.1 Fixed weir

The *fixed weir*-option employs a power function based ‘stage-discharge’ relationship  $q_{dis}(\phi_{sur})$  for which the parameters in the input are specified in SI-units<sup>1</sup> or a tabulated relationship. The power function based ‘stage-discharge’ relationship reads as:

$$q_{dis} = \frac{Q_{dis}}{A_{cu}} = \frac{\alpha_{weir} (\phi_{sur} - z_{weir})^{\beta_{weir}}}{A_{cu}} \quad (5.6)$$

in which  $Q_{dis}$  is the volumetric discharge ( $m^3 s^{-1}$ ),  $A_{cu}$  is the area of the control unit ( $m^2$ ),  $z_{weir}$  is the weir crest level (m),  $\alpha_{weir}$  is the discharge coefficient ( $m^{3-\beta} d^{-1}$ ) and  $\beta_{weir}$  is the discharge exponent (-). For a broad-crested rectangular weir,  $\alpha_{weir}$  is (approximately) given by  $\alpha_{weir} = 1.7 \times \text{"weir width"}$ . The stage-discharge relationship can optionally be specified by a table. In that case the relationship should be defined for each management period.

<sup>1</sup> Literature values are often given in these units. The conversion to internal units is handled by SWAP.

### 5.1.2.2 Soil moisture controlled weir management

This model option assumes the target level of a weir to be controlled by one or more soil moisture state variables. The so called water management scheme defines the setting of the water level  $\phi_{sur,tar}$  aimed for in relation to a soil moisture state variable. The target level is defined as a combinational function of three state variables related to soil moisture:

1. the average groundwater level  $\phi_{avg}$  (cm). Lower target levels a higher groundwater levels may prevent waterlogging and can contribute to minimize crop yield reduction.
2. the soil water pressure head  $h$  (cm) at a certain depth. A soil water pressure value appears to be a better indicator for water logging in nature reserves than a groundwater level criteriumPar.
3. the capacity of the unsaturated soil profile to store water  $V_{uns}$  (cm). This state variable is an indicator for the possibility of buffering extreme rainfall events. Maintaining a certain minimum amount of storage, reduces the risk of flooding and subsequent discharge peaks.

During the simulation, the SWAP model selects the target level for which all three criteria are met. A scheme maintained by a soil moisture controlled weir is illustrated in Table 5.1. The minimum target level is specified in the first column. The second, third and fourth column represent values for the corresponding groundwater level, soil water pressure head and soil water storage capacity. The first row contain zeros, indicating that irrespective the conditions, the minimum target level should never drop below that level.

**Table 5.1** Example of a water management scheme, with  $\phi_{sur,tar}$  as the target level, the groundwater level criterium  $\phi_{avg,max}$ , the pressure head criterium  $h_{max}$  and the soil water storage criterium  $V_{uns,min}$ .

$\phi_{sur,tar}$ (cm)	$\phi_{avg,max}$ (cm)	$h_{max}$ (cm)	$V_{uns,min}$ (cm)
-180	0	0	0
-160	-80	-100	1.5
-140	-90	-150	2.0
-120	-100	-200	2.5
-100	-120	-250	3.0
-80	-130	-300	4.0

To avoid the target level reacting too fast on the prevailing groundwater level, a *maximum drop rate* parameter has been introduced specifying the maximum permitted change of the target level per time unit (cm d<sup>-1</sup>). The limitation of the target level change can become effective in periods with surface water supply combined with a rising groundwater level.

In periods with heavy rainfall and high discharge, the maximum capacity of a soil moisture controlled weir can be reached and the crest level will drop to its minimum level. Then, the surface water level is not controlled by any of the criteria mentioned before any longer, but will be a function of the discharge characteristics of the surface water infrastructure. Therefore, the management scheme of a soil moisture controlled weir should always be combined with a table defining a stage discharge relationship. This tabulated relationship should be defined for every management period. The minimum level of management scheme should identical to the minimum level of the discharge relationship.

---

## 5.2 User instructions

### 5.2.1 Input instructions

The user first has to select the option for extended drainage (Box 5.1).

Box 5.1 Extended drainage option in drainage file \*.DRA.

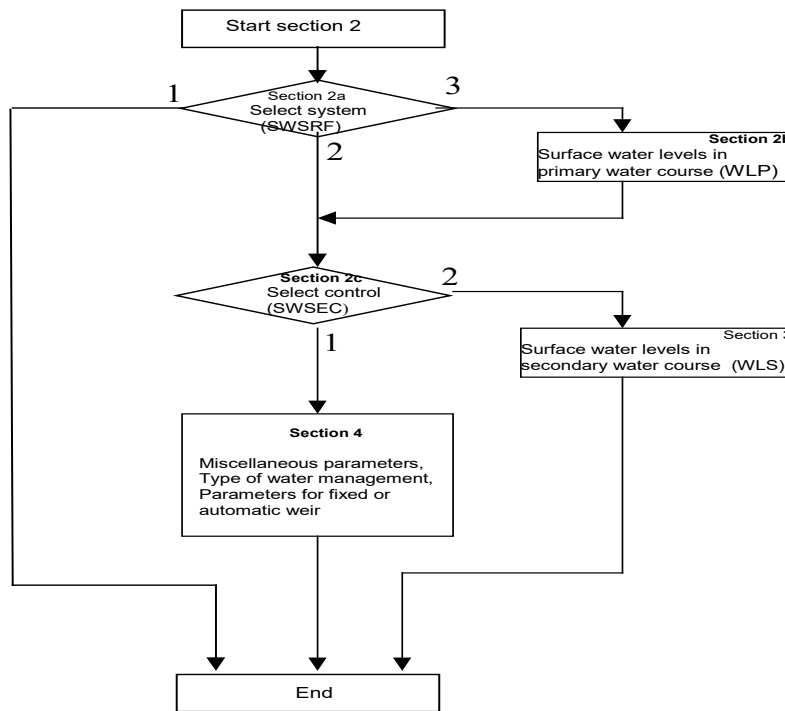

```
*** LATERAL DRAINAGE SECTION ***  
  
*****  
* Specify whether lateral drainage should be included  
  
  SWDRA = 2 ! Switch, simulation of lateral drainage:  
            ! 0 = No simulation of drainage  
            ! 1 = Simulation with basic drainage routine  
            ! 2 = Simulation with extended drainage routine (incl surf water man.)  
  
* If SWDRA = 1 or SWDRA = 2 specify name of file with drainage input data:  
  DRFIL = 'wg02' ! File name with drainage input data, no extension [A16]  
  
*****
```

Parameters and input variables are specified in a separate file called DRFIL. The input data are given in 2 sections:

- Section 1: drainage characteristics (described in Chapter 4)
- Section 2: surface water system (described in Chapter 5)

In Section 1, the user should specify the altitude of the control unit (= soil surface), with respect to a certain reference level (ALTCU). In Section 2, water management levels are given with respect to the same reference. The user may choose to define the soil as surface reference level by specifying zero for the altitude.

A flow chart of the input for the surface water module (Section 2 in the input file) is given in Figure 5.1. The user should make selections for the kind of surface water system (SWSRF) and the kind of control (SWSEC). The different parts of Section 2 are described hereafter.

**Figure 5.1** Flow chart for input data of surface water system

Section 2 starts with a switch (Section 2a, variable SWSRF) for three options:

1. no surface water system is simulated;
2. surface water system is simulated with no separate primary water course;
3. surface water system is simulated with a primary water course (level 1) separate from the control unit

If the first option (SWSRF=1) has been chosen, the user may skip the rest of Section 2. For the second or third option (SWSRF=2 or 3) the user has also to specify how the surface water level in the control unit is determined (Section 2c, variable SWSEC):

1. the surface water level is simulated;
2. the surface water level is obtained from input data.

If the third option (SWSRF=3) has been chosen, the user should also specify (Section 2b) the time variation of the surface water level in the primary water course. The specification is done in terms of data pairs (date, water level). To obtain levels at intermediate dates, the model performs a linear interpolation.

Box 5.2 Global options for interaction with surface water in drainage file \*.DRA.

```

*****
* Part 2a: Specification and control of surface water system
*
  SWSRF = 2 ! option for interaction with surface water system [1..3, I]
*       1 = no interaction with surface water system
*       2 = surf. water system is simulated with no separate primary system
*       3 = surf. water system is simulated with separate primary system
*****
*
* Part 2b: Surface water level of primary system
*
* Only if SWSRF = 3 then the following table must be entered
* Table with Water Levels in the Primary system [max. = 52]:
* no levels above soil surface for primary system
*
* Water level in primary water course WLP [ALTCU-1000..ALTCU-0.01 cm, R] as
* function of DATE1 [dd-mmm-yyyy]
  DATE1      WLP
02-jan-1980  -100.

*End_of_table
*****
*
* Part 2c: Surface water level of secondary system
*
* If SWSRF = 2 or 3 then the variable SWSEC must be entered
*
  SWSEC = 2 ! option for surface water level of secondary system [1..2, I]
*       1 = surface water level is input
*       2 = surface water level is simulated
*****

```

If the option is chosen to obtain surface water levels from input data (SWSEC=1), the surface water level of the secondary watercourse has to be specified in the form of data pairs (Section 3).

If the option is chosen to simulate surface water levels (SWSEC=2), the user has to specify how the surface water system in the control unit functions and how it is managed (Section 4).

Section 4 starts with some miscellaneous parameters (Section 4a):

- the initial surface water level in the control unit;
- the criterium for detecting oscillation of the surface water level;
- the number of water management periods.

In the next Section 4b the management period are defined as well as the type of watermanagent (1- fixed weir crest; 2- automatic weir), the water supply capacity and a tolerance value (WLDIP). The tolerance value WLDIP relates the water supply level to the target level preventing oscillations and too fast unrealistic responses of surface water management to the prevailing conditions. This tolerance can be seen as the allowed dip of the surface water level and can take a value of e.g. 10 cm. An appropriate setting of this parameter can save a substantial amount of water.

```

Dependent on the discharge relationship for the weir, the user has to specify:

- either Section 4c (SWQHR=1, exponential relation)
- or Section 4d (SWQHR=2, relation given as table)

If an exponential relations is chosen then, for each water management period with a fixed weir crest using weir characteristics, the user should specify (Section 4c):

- Size of the control unit (catchment) (ha);
- A table with weir characteristics for each management period:
  - Index for management period (-);
  - Elevation (H) of the weir crest (cm);
  - dischargecoefficient  $\alpha_{input}$  ( $m^{3-\beta} s^{-1}$ );
  - discharge exponent  $\beta$  (-)

Head-discharge relationships are given in SI-units, i.e. m for length and s for time and the discharge is computed as a volume rate ( $m^3 s^{-1}$ ). To facilitate the input for the user we conformed to hydraulic literature. This implies that the user has to specify the weir characteristics that define a relationship of the following form:

$$Q = \alpha_{input} H^\beta \tag{5.7}$$

where  $Q$  is the discharge ( $m^3 s^{-1}$ ),  $H$  is the head above the crest (m) and  $\alpha_{input}$  is a weir coefficient ( $m^{3-\beta} s^{-1}$ ),  $\beta$  is a weir exponent (-).

The preparatory work that the user has to do is to compute the value of  $\alpha_{input}$  from the various coefficients preceding the upstream head above the crest. For instance, for a broad-crested rectangular weir,  $\alpha_{input}$  is (approximately) given by:

$$\alpha_{input} = 1.7 b \tag{5.8}$$

where 1,7 is the discharge coefficient of the weir (based on SI-units),  $b$  is the width of the weir (m). To correct for units, SWAP carries out the following conversion:

$$\alpha_{weir} = \frac{8.65 * 100^{(1-\beta)}}{A_{cu}} \tag{5.9}$$

where  $A_{cu}$  is the size of the control unit (ha)

The model requires input of the size of the control unit ( $A_{cu}$ ), which in simple cases will be identical to the size of the simulation unit.

If the discharge relation is described using a table (SWQHR=2) then, for each water management period with a fixed weir crest using weir characteristics, the user should specify a table in Section 4d.

In Section 4e of the input file the required parameters should be given to introduce an automatic weir (SWMAN=2) controlled by soil moisture characteristics (see also Par. 5.1.2.2). For each management period with an automatic weir the user should specify in Section 4e:

- the maximum allowed drop rate of the water level setting
- the depth (HDEPTH) in the soil profile for a comparison between simulated and required soil moisture criterium (HCRIT)

The three state variables (GWLCRIT, HCRIT, VCRIT) that define the target weir level are given in a separate table.

# 6 Macropore flow

In structured soils such as clay and peat, preferential flow occurs through large pores or macropores in the (un)saturated soil matrix. Macropores are defined as pores with a diameter or width equal to or larger than 100  $\mu\text{m}$ . Macroporosity can be caused by shrinking and cracking of soil, by plant roots, by soil fauna, or by tillage operations.

Due to the very rapid flow through macropores, water and solutes can reach large depths almost immediately after the start of a shower, bypassing the capacity of the soil matrix for storage, adsorption and transformation of potential pollutants. This process is known as 'bypass flow' or 'short-circuiting' (Hoogmoed and Bouma, 1980). Because of the great impact of macropores on water flow and solute transport through the vadose zone, a concept has been implemented in SWAP for simulating preferential flow at the field scale.

Cracked clay soils reveal a large spatial variability of water contents and solute concentrations at given depth (Beven and Germann, 1982; Bronswijk et al., 1995). Therefore, instead of trying to describe water flow and solute transport at each location, the field-average behaviour may be easier to catch in a model. In order to make the model suitable for process and scenario analysis, concepts should be used that are generally applicable, thus physically based. Furthermore, model calibration requires a limited number of parameters, and preferably parameters that can be measured directly in the field. The description of macropore flow in SWAP has been developed taking into account these requirements.

The macropore flow concept is described by Hendriks et al. (in prep). It is new in the present SWAP and therefore, and to promote a well-considered use of this option its description is rather extensive and detailed. The concept of macropore flow is described in Section 6.1. The numerical implementation in the SWAP model is discussed in Section 6.2. User instructions are given in Section 6.3.

## 6.1 Concept

In the SWAP model macropore water flow includes the following processes:

- uptake of water by macropores at the soil surface;
- vertical transport to deeper layers or the groundwater bypassing the soil matrix;
- lateral infiltration into and exfiltration out of the soil matrix;
- rapid drainage to drainage systems;
- water storage in the macropores.

The simulation of these processes is based on the description of the macropore geometry as proposed by Hendriks et al. (1999). The description of this geometry that SWAP uses, is discussed in Section 6.1.1. Water flowing into macropores is instantaneously added to the water storage at the bottom of the macropores. Lateral infiltration into the soil matrix of macropore water running rapidly downwards is neglected. Because such downward flow occurs in a low number of contracted films, contact areas with the matrix are small, and consequently this infiltration is negligible (Hoogmoed and Bouma, 1980; Bootink, 1993). Some of the macropore inflow is trapped in discontinuous macropores and is therefore forced to infiltrate into the unsaturated matrix at different depths. This process is called 'internal catchment' (Bouma and Dekker, 1978; Van Stiphout et al., 1987). The water flow and balance are described in more detail in Section 6.1.2.

---

### 6.1.1 Macropore geometry

In SWAP the geometry of macropore structure is described by characterising the macropore volume according to three main properties:

1. **Continuity**: vertical continuity controls flow of water that is taken up at the soil surface to different depths in the profile and horizontal continuity controls exchange of water between macropores (Section 6.1.1.1);
2. **Persistency**: static macropore volume is permanent, while dynamic macropore volume (shrinkage cracks) depends on soil moisture status (Section 6.1.1.2);
3. **Horizontal distribution**: in the horizontal plane, macropore volume is distributed over cracks and holes. The shape of the horizontal cross-section of the macropore volume has a large impact on the water exchange between macropore volume and soil matrix, and on rapid drainage (Section 6.1.1.3).

The concept provides a functional rather than a meticulous description of these macropore geometry properties. With a limited number of input parameters it determines a functional macropore bottom depth distribution, and magnitude and horizontal shape of the macropore volume as a function of depth.

A basic assumption in the concept is that property 'persistency' is not correlated with both other properties. 'Persistency' refers to volume and not to pore structure: static macropore volume and dynamic macropore volume form together the total macropore volume. Characterisation according to the other two properties applies to the total volume. The properties 'continuity' and 'horizontal distribution' are correlated: the horizontal macropore volume distribution as a function of depth depends on the macropore bottom depth distribution.

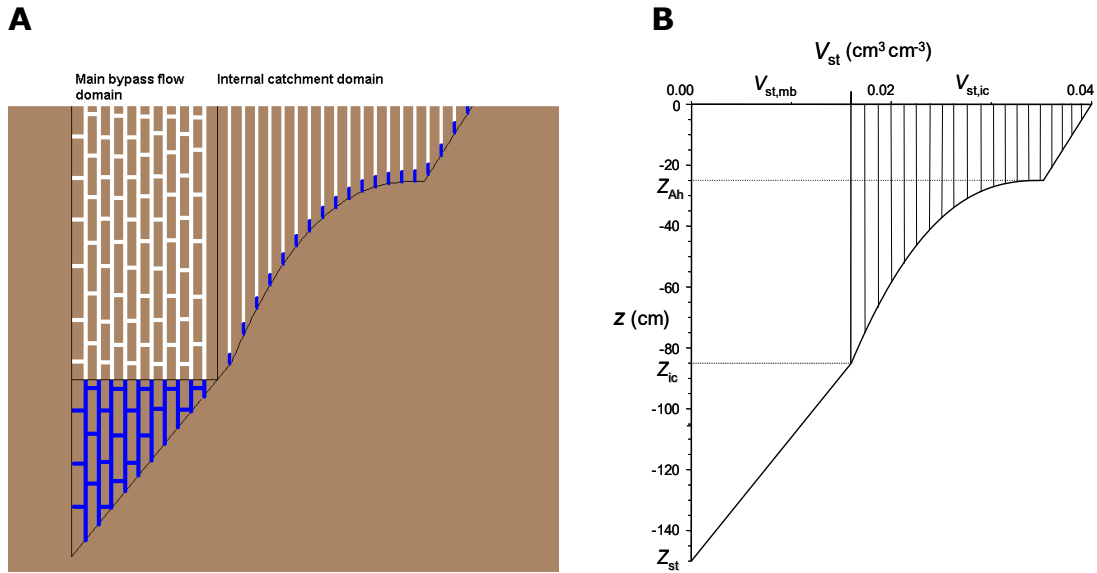

#### 6.1.1.1 Continuity

With respect to vertical and horizontal continuity the macropores are divided into two classes that are integrated in two domains:

1. Main Bypass (MB) flow domain: the network of continuous, horizontal interconnected macropores;
2. Internal Catchment (IC) domain: discontinuous non-interconnected macropores, ending at different depths.

The MB domain represents the main system of continuous structural and shrinkage cracks, as well as root and worm holes. These macropores penetrate relatively deep into the soil profile and are assumed to be horizontal interconnected, for example in a network of structural and shrinkage cracks. In the MB domain water is transported relatively fast and deep into the profile bypassing the soil matrix. This may lead to short-circuiting between soil surface and groundwater, and rapid drainage to drains.

The IC domain represents macropores – cracks and holes – that are not interconnected and not connected to the MB domain, and that end at different depths in the profile. In this domain macropore inflow is entrapped at the bottom of individual macropores, resulting in forced infiltration of macropore water into the (mainly) unsaturated soil matrix at different, relatively shallow depths.

**Figure 6.1** Aschematic representation of the two main domains: 1) Main bypass flow domain (MB): transporting water deep into the profile and possibly leading to rapid drainage, 2) Internal catchment domain (IC): infiltration of trapped water into the (mainly) unsaturated matrix at different depths; B: mathematical description of the two domains, as static macropore volume fraction  $V_{st}$  as a function of depth for the MB ( $V_{st,mb}$ ) and IC ( $V_{st,ic}$ ) domain, with the IC domain divided in several sub-domains.

Figure 6.1.A presents a conceptual visualisation of the two classes of macropores; Figure 6.1.B depicts a mathematical representation of the conceptual figure. It describes the static macropore volume fraction  $V_{st}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) of the two domains,  $V_{st,mb}$  and  $V_{st,ic}$ , as a function of depth. From these two volume fractions the partition of the static macropore volume over the two domains at any depth can be calculated. This partition as a function of depth is a crucial property of macropore geometry in the concept. It determines the distribution of macropore volume and water flow over both domains. It is expressed in the volumetric proportion  $P_{dm}$  (-) of each domain  $dm$ :

$$P_{mb} = \frac{V_{st,mb}}{V_{st,mb} + V_{st,ic}} \quad \text{and} \quad P_{ic} = \frac{V_{st,ic}}{V_{st,mb} + V_{st,ic}} \quad (6.1)$$

and

$$P_{mb} = 1 - P_{ic} \quad (6.2)$$

where subscripts 'mb' and 'ic' refer to MB and IC domains, respectively.

In the concept, static macropore volume is not necessary always present. But even in the absence of this volume the volumetric proportions are required to partition the dynamic volume over the domains. Therefore, the calculation of the volumetric proportions as a function of depth is independent of the magnitude of the dynamic macropore volume. This calculation provides the 'blueprint' of the macropore domains. In order to visualize this 'blueprint' it is more illustrative to show only the static macropore volume as is done in Figure 6.1.B. Since the dynamic volume changes with time and depth, depending on shrinkage characteristic and soil moisture status that may differ at each depth, it would distort the image of the 'blueprint'.

The volumetric proportion of each domain as a function of depth is described by analytical equations with four basic input parameters: two depths (cm),  $Z_{Ah}$  representing the bottom of the A-horizon and  $Z_{ic}$  representing the bottom of the IC domain, proportion  $P_{ic,0}$  (-) of the IC domain at soil surface and power  $m$  (-), a shape factor. In order to describe the individual IC macropores, the IC domain is divided into sub-domains. Strictly speaking, this subdivision of the IC macropore volume is an aspect of the numerical implementation and therefore is discussed in Section 6.2.1.1.

The IC volumetric proportion at the soil surface  $P_{ic,0}$  is an essential parameter of the concept. It determines the distribution over the two main domains of the precipitation water routed into the macropores at the soil surface, the major source of macropore water. It is assumed that the IC macropore volume consists of many individual small macropores that originates at the soil surface and functional end at different depths. In this sense 'functional' implies that flow is blocked at the depth of ending of the macropores. Thus, the functional volume of IC macropores gradually declines to zero at depth  $Z_{ic}$ .

**Figure 6.2** Cumulative frequency distribution  $R$  of the depth  $z$  at which the functional IC macropores end and the fraction  $F$  of IC macropores that is functional at depth  $z$ .

The cumulative frequency distribution of the depth  $z$  at which the functional IC macropores end in the concept is described with a power law function (Figure 6.2):

$$R = R_{Z_{Ah}} \frac{z}{Z_{Ah}} \quad \text{for } 0 \geq z > Z_{Ah} \quad (6.3.a)$$

$$R = R_{Z_{Ah}} + (1 - R_{Z_{Ah}}) \left( \frac{Z_{Ah} - z}{Z_{Ah} - Z_{ic}} \right)^m \quad \text{for } Z_{Ah} \geq z \geq Z_{ic} \quad (6.3.b)$$

where the depths  $z$ ,  $Z_{Ah}$  and  $Z_{ic}$  (cm) are defined negative downwards and the power  $m$  (-) is a shape-factor. Power  $m < 1$  describes shallow IC systems, while  $m > 1$  describes deep IC systems;  $m = 1$  describes an intermediate system with a linear decline of functional IC macropores with depth.  $R_{Z_{Ah}}$  (-) is an optional parameter with which a linear increase of the  $R$ -curve over the thickness of the A-horizon can be described. Its default value is zero.

Curve  $F$  in Figure 6.2 depicts the complement of  $R$ , the cumulative frequency distribution of the depth at which IC macropores are not ended in the concept, i.e. the fraction of IC macropores that is functional at that depth  $z$ . Functional in the sense of downward transport and storage of water, and lateral infiltration of macropore water into the soil matrix:

$$F = 1 - R \quad (6.4)$$

The volumetric proportion of IC macropore volume as a function of depth can be written in terms of the constant  $P_{ic,0}$  and the function  $F$ :

$$P_{ic} = \frac{F}{\frac{1}{P_{ic,0}} + F - 1} \quad \text{for } 0 \geq z > Z_{ic} \quad \text{and} \quad 0 < P_{ic,0} \leq 1 \quad (6.5.a)$$

$$P_{ic} = 0 \quad \text{for } z \leq Z_{ic} \quad \text{and/or for } P_{ic,0} = 0 \quad (6.5.b)$$

The volumetric proportion of MB macropore volume as a function of depth is calculated from function  $P_{ic}$  with Eq. (6.2). This results in a proportion  $P_{mb}$  of 1 for depths below  $Z_{ic}$  where IC macropore volume is absent and all macropore volume is MB volume.

### 6.1.1.2 Persistency

With respect to persistency the macropore volume of each of the domains consists of:

1. Static macropore volume, expressed as volume fraction  $V_{st}$  ( $\text{cm}^3 \text{cm}^{-3}$ ): macropores that are permanent present. The static volume as a function of depth is constant in time;
2. Dynamic macropore volume, expressed as volume fraction  $V_{dy}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) i.e. shrinkage cracks. The dynamic volume as a function of depth is not constant in time.

The dynamic shrinkage volume is added up to the static volume, if present, and in this way enlarges the total macropore volume (Figure 6.3). The total macropore volume fraction  $V_{mp}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) is distributed over the two domains according to their volumetric proportion:

$$V_{mp} = V_{st} + V_{dy} \quad (6.6.a)$$

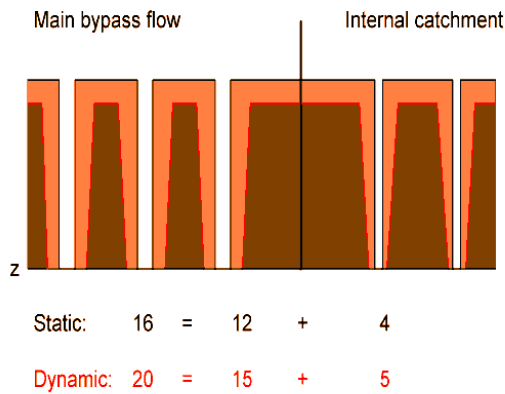

$$V_{mb} = P_{mb} V_{mp} = P_{mb} (V_{st} + V_{dy}) = V_{st,mb} + P_{mb} V_{dy} \quad (6.6.b)$$

$$V_{ic} = P_{ic} V_{mp} = P_{ic} (V_{st} + V_{dy}) = V_{st,ic} + P_{ic} V_{dy} \quad (6.6.c)$$

This implies that below depth  $Z_{ic}$  all dynamic volume is part of the MB domain. And below depth  $Z_{st}$  only dynamic volume may occur.

#### Static macropore volume

The static macropore volume consists of structural shrinkage cracks, bio-pores (e.g., worm and root holes) and macropores that originate from tillage operations. Contrary to dynamic macropore volume, it is independent of the soil moisture status. The volume fraction of static macropores  $V_{st}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) as a function of depth  $z$  is described with the constant  $P_{ic,0}$ , the function  $F$  (Eq. (6.4)) and the two additional input parameters  $V_{st,0}$  (-), describing the volume fraction of static macropores at the soil surface, and  $Z_{st}$  (cm), signifying the depth of static macropores.

**Figure 6.3** Partitioning of static and dynamic macropore volume over the two macropore domains according to the volumetric proportions of the domains ( $P_{ic} = 0.25$ ): ratio between MB and IC domains is equal for static and dynamic macropore volume. White areas represent static and light areas dynamic macropore volume. Dark colour is the soil matrix. Numbers are imaginary macropore volumes meaning: Total = Main Bypass + Internal Catchment.

In general (all  $V$  in  $\text{cm}^3 \text{cm}^{-3}$ ):

$$V_{\text{st}} = V_{\text{st,mb}} + V_{\text{st,ic}} \quad \text{and thus} \quad V_{\text{st},0} = V_{\text{st,mb},0} + V_{\text{st,ic},0} \quad (6.7.a)$$

where:

$$V_{\text{st,ic},0} = P_{\text{ic},0} V_{\text{st},0} \quad \text{and} \quad V_{\text{st,mb},0} = (1 - P_{\text{ic},0}) V_{\text{st},0} \quad (6.7.b)$$

The static macropore volume fraction of the MB domain as a function of depth is calculated as:

$$V_{\text{st,mb}} = V_{\text{st,mb},0} \quad \text{for } 0 \geq z > Z_{\text{ic}} \quad (6.8.a)$$

$$V_{\text{st,mb}} = V_{\text{st,mb},0} \frac{z - Z_{\text{st}}}{Z_{\text{ic}} - Z_{\text{st}}} \quad \text{for } Z_{\text{ic}} \geq z > Z_{\text{st}} \quad (6.8.b)$$

$$V_{\text{st,mb}} = 0 \quad \text{for } z \leq Z_{\text{st}} \quad (6.8.c)$$

And the static macropore volume fraction of the IC domain as a function of depth:

$$V_{\text{st,ic}} = F V_{\text{st,ic},0} \quad \text{for } 0 \geq z > Z_{\text{ic}} \quad (6.9.a)$$

$$V_{\text{st,ic}} = 0 \quad \text{for } z \leq Z_{\text{ic}} \quad (6.9.b)$$

#### *Dynamic macropore volume*

The dynamic macropore volume originates from the shrinking of the soil matrix due to soil moisture loss. In general, this process is restricted to soils that contain substantial amounts ( $> 10\text{-}15$  mass-%) of clay minerals (except kaolinite) and/or organic matter. Mostly, the shrinkage volume occurs as shrinkage cracks. But shrinkage of the matrix may also enlarge cylinder-shaped macropores. In SWAP it is assumed that shrinkage enlarges the present permanent macropore volume and consequently the shrinkage volume is added up to the static volume (Eq. (6.3)).

Soil matrix shrinkage occurs in vertical and horizontal direction. Vertical shrinkage leads to soil surface subsidence, horizontal shrinkage to dynamic macropore volume. The dynamic volume is calculated from overall and vertical shrinkage as:

$$V_{\text{dy}} = V_{\text{sh}} - V_{\text{su}} \quad (6.10)$$

where  $V_{\text{sh}}$ ,  $V_{\text{dy}}$  and  $V_{\text{su}}$  (all in  $\text{cm}^3 \text{cm}^{-3}$ ) are the volume fraction of overall matrix shrinkage, the dynamic macropore volume fraction and the subsidence volume fraction, respectively.

In the present version of SWAP the vertical shrinkage does not affect the vertical coordinate system of SWAP. This approach avoids numerical problems that may result from solving Richards equation for a dynamical vertical coordinate. We assume that at the field scale the effects of ignoring changes of the soil matrix in vertical direction are small as compared to effects of uncertainties in other processes and input parameters.

However, the approach of ignoring vertical changes in soil matrix does affect the calculation of the dynamic macropore volume. This volume is corrected for the vertical shrinkage according to:

$$V_{\text{dy}} = \frac{V_{\text{sh}} - V_{\text{su}}}{1 - V_{\text{su}}} \quad (6.11)$$

In this way the ratio between  $V_{\text{dy}}$  on one hand, and the matrix volume fraction and the static macropore volume fraction  $V_{\text{st}}$  on the other hand is consistent.

If static macropore volume is present, the horizontal area fraction of the matrix equals  $1 - V_{\text{st}} \text{cm}^2 \text{cm}^{-2}$  and consequently the dynamic macropore volume fraction is calculated as:

$$V_{\text{dy}} = (1 - V_{\text{st}}) \frac{V_{\text{sh}} - V_{\text{su}}}{1 - V_{\text{su}}} \quad (6.12)$$

The vertical shrinkage component is determined from the overall matrix shrinkage as (Bronswijk, 1988):

$$V_{su} = 1 - (1 - V_{sh})^{\frac{1}{r_s}} \quad (6.13)$$

where exponent  $r_s$  (-) is the geometry factor (Rijniersce, 1983). In case of three-dimensional isotropic shrinkage,  $r_s = 3$ . When cracking dominates subsidence  $r_s > 3$ , when subsidence dominates cracking  $1 < r_s < 3$ . In case of subsidence only,  $r_s = 1$ . The geometry factor is an input parameter.

The matrix shrinkage volume fraction  $V_{sh}$  is a function of volumetric moisture content and shrinkage characteristic. A shrinkage characteristic describes the relationship between soil volume and soil moisture content. Many forms of shrinkage characteristics exist. A very convenient one is the characteristic that takes the constant volume fraction of the solid soil fraction  $V_{sol}$  as reference for all variable volume fractions and expresses the soil matrix volume fraction  $V_m$  in terms of pore volume fraction  $V_p$  relative to  $V_{sol}$  (Bronswijk, 1988) (all  $V$  in  $\text{cm}^3 \text{cm}^{-3}$ ):

$$V_m = V_{sol} + V_p = (1 + e)V_{sol} \quad (6.14)$$

where  $e$  ( $\text{cm}^3 \text{cm}^{-3}$ ) is the void ratio:

$$e = \frac{V_p}{V_{sol}} \quad (6.15)$$

The shrinkage volume fraction  $V_{sh}$  is equal to the fraction of volume loss of the matrix that in its turn equals the fraction loss of pore volume. The latter is expressed in terms of  $e$  and  $V_{sol}$ :

$$V_{sh} = -\Delta V_m = -\Delta V_p = -\Delta e V_{sol} = -(e - e_s)V_{sol} \quad (6.16)$$

where  $e_s$  is the void ratio at saturation.

The shrinkage characteristic expresses the variable  $e$  as a function of the variable  $\vartheta$  ( $\text{cm}^3 \text{cm}^{-3}$ ), which represents the moisture ratio:

$$e = f(\vartheta) \quad (6.17.a)$$

where the moisture ratio is defined as:

$$\vartheta = \frac{V_w}{V_{sol}} = \frac{\theta}{1 - \theta_s} \quad (6.17.b)$$

with  $V_w$  ( $\text{cm}^3 \text{cm}^{-3}$ ) the actual water volume fraction that equals  $\theta$ , the volumetric moisture content of the matrix. Volume fraction of solids  $V_{sol}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) equals  $1 - \theta_s$  ( $\theta_s = \theta$  at saturation).

The exact form of the shrinkage characteristic depends on soil texture, in terms of content and nature of clay minerals, and organic matter. Shrinkage characteristics of clay and organic soils – peat and peaty soils – differ strongly.

#### *Shrinkage characteristic of clay and clayey soils*

Figure 6.4.A shows a typical shrinkage characteristic of a clay soil. Three stages can be distinguished (Stroosnijder, 1975; Bronswijk, 1988):

1. Normal shrinkage: volume decrease of clay aggregates is equal to moisture loss. The aggregates remain fully saturated;
2. Residual shrinkage: upon drying the volume of the aggregates still decreases, but moisture loss is greater than volume decrease. Air enters the pores of the aggregates;
3. Zero shrinkage: soil particles reach their most dense configuration. Upon further moisture extraction, the volume of the aggregates remains constant. Moisture loss equals air volume increase of the aggregates. Rigid soils, like sands, only show this stage.

A fourth shrinkage stage that precedes normal shrinkage may be recognized: structural shrinkage. When saturated soils dry, large water filled pores may be emptied. As a result, aggregates can get a

somewhat denser packing. Overall, the volume changes in this stage are negligible, but water losses can be considerable. In SWAP, structural shrinkage is explicitly accounted for in the form of the static macropores, e.g. structural shrinkage cracks. The first three real shrinkage stages are computed as a function of moisture content with the equation of Kim (1992):

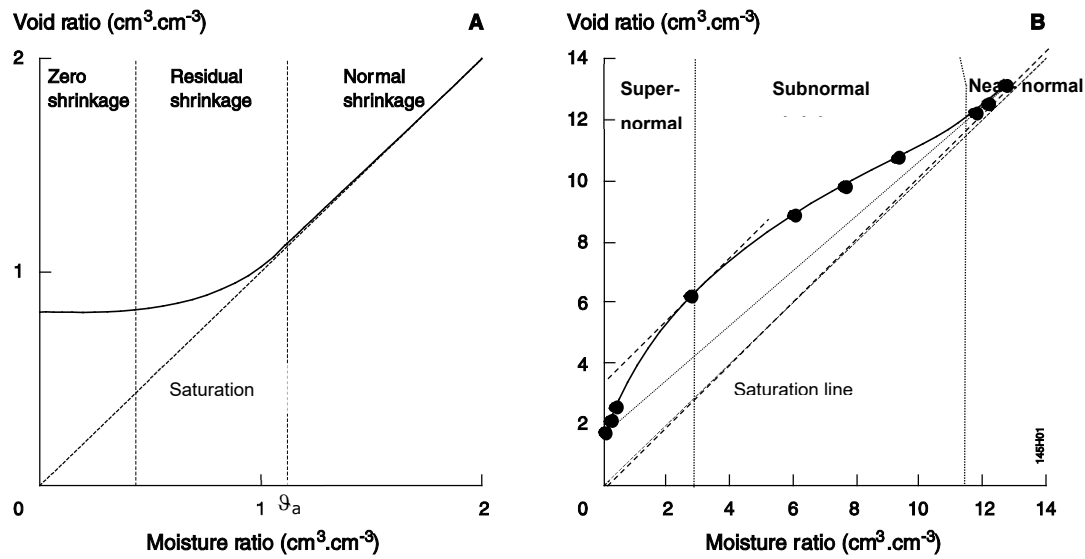

$$e = \alpha_K \exp(-\beta_K \vartheta) + \gamma_K \vartheta \text{ for } 0 < \vartheta < \vartheta_s \quad \text{where} \quad \vartheta_s = \frac{\theta_s}{1-\theta_s} \quad (6.18)$$

with  $\alpha_K$  ( $\text{cm}^3 \text{cm}^{-3}$ ) equals  $e_0$  the void ratio at  $\vartheta = 0$ ,  $\beta_K$ , and  $\gamma_K$  are dimensionless fitting parameters and  $\vartheta_s$  is void ratio at saturation. Using Eq. (6.18),  $e$  may become smaller than  $e_0$ , in which case the model sets  $e$  to  $e_0$  (zero shrinkage).

#### Shrinkage characteristic of peat and peaty soils

According to Hendriks (2004), for peat soils three shrinkage stages can be distinguished as well (Figure 6.4.B):

1. Near-normal shrinkage: volume reduction equals nearly moisture loss, little air enters the pores and the peat matrix remains close to saturation;
2. Subnormal shrinkage: upon drying moisture loss exceeds volume reduction, air enters the relatively large pores while the small pores in the organic fibres, that form the 'skeleton' around the larger pores, remain water-filled;
3. Supernormal shrinkage: volume reduction exceeds by far moisture loss, small pores are emptied and the skeleton collapses, so that air is driven out of the larger pores and the matrix reaches its final, smallest volume when the moisture content is zero.

**Figure 6.4** Typical shrinkage characteristic of A. clay (modified after Bronswijk, 1988) and B. peat (after Hendriks, 2004), expressed as void ratio  $e$  as a function of moisture ratio  $\vartheta$ , showing the three shrinkage stages. Black dots in B. are measurements while solid line is fit with Eq.(6.19).

Hendriks' (2004) equation for the shrinkage curve of peat and peaty soils reads:

$$e = e_t \left( 1 + P_H \frac{\vartheta_t^{\alpha_H} (\exp(-\beta_H \vartheta_t) - \exp(-\beta_H))}{\vartheta_{t,P}^{\alpha_H} (\exp(-\alpha_H) - \exp(-\beta_H))} \right) \text{ for } 0 < \vartheta < \vartheta_a \quad (6.19.a)$$

$$e = e_t \text{ for } \vartheta_a \leq \vartheta < \vartheta_s \quad (6.19.b)$$

with:

$$e_t = e_0 + (e_s - e_0) \frac{\vartheta}{\vartheta_s}; e_s = \vartheta_s = \frac{\theta_s}{1-\theta_s} \quad (6.19.c)$$

$$\vartheta_t = \frac{\vartheta}{\vartheta_a} ; \vartheta_{t,P} = \frac{\alpha_H}{\beta_H} \quad \text{for } 0 < \alpha_H < \beta_H \quad (6.19.d)$$

where  $\vartheta_a$  is the moisture ratio at the transition of the near-normal shrinkage stage to the subnormal shrinkage stage, when air entry increases substantially.  $\alpha_H$ ,  $\beta_H$  and  $P_H$  are dimensionless fitting parameters.

#### Overburden pressure

Shrinking and swelling behaviour in the field may deviate from that in the laboratory because of overburden pressure of overlaying soil layers in the field. This may result in delayed horizontal shrinkage in favour of vertical shrinkage. To account for this process, a threshold moisture content  $\theta_{\text{crack}}$  is introduced. For moisture contents  $\theta \geq \theta_{\text{crack}}$  all shrinkage is vertical and for  $\theta < \theta_{\text{crack}}$  shrinkage is vertical and horizontal according to geometry factor  $r_s$ . This concept does not apply to swelling: shrinkage cracks are not closed before saturation.  $\theta_{\text{crack}}$  is an input parameter.

#### 6.1.1.3 Horizontal distribution

In the horizontal plane in the field, macropore volume is distributed over different forms of macropores: from holes with a diameter of 100  $\mu\text{m}$  to several centimetres wide, several decimetres long cracks. This distribution determines the functional horizontal shape of the macropores, which forms the basis of the calculation of several important parameters:

1. two parameters that affect lateral water exchange between macropores and soil matrix:
  - a. the vertical area of macropore walls per unit of volume, and
  - b. the distance from macropore wall to centre of matrix polygons;
2. the lateral hydraulic conductivity of cracks in case of rapid drainage.

For simplicity and input parameter limitation, cracks and hole-shaped macropores are not explicitly distinguished. Instead, they are implicit in an effective functional horizontal macropore shape that is described by an effective matrix polygon diameter  $d_{\text{pol}}$  (cm) as a function of depth.

Assuming effective regular soil matrix polygons, the effective vertical area of macropore walls per unit of volume  $A_{\text{wall}}^*$  ( $\text{cm}^2 \text{cm}^{-3}$ ) is equal to the quotient of the perimeter divided by the area of the polygons. For all even-sided regular polygons, from square to circle, this quotient equals (see Appendix 2 for derivation):

$$A_{\text{wall}}^* = \frac{4}{d_{\text{pol}}} \quad (6.20)$$

The effective horizontal distance  $x_{\text{pol}}$  (cm) from macropore wall to matrix polygon centre is taken equal to:

$$x_{\text{pol}} = \frac{1}{2} d_{\text{pol}} \quad (6.21)$$

The effect of horizontal macropore shape on rapid drainage is expressed through the effect on the lateral hydraulic conductivity of cracks which depends on the effective crack width  $w_{\text{cr}}$  (cm) (see Section 6.1.2.3). This width is calculated from the effective polygon diameter and the volume fraction  $V_{\text{mb}}$  of macropores in the MB domain (see 0 for derivation):

$$w_{\text{cr}} = d_{\text{pol}} \left( 1 - \sqrt{1 - V_{\text{mb}}} \right) \quad (6.22)$$

It is assumed that the effective diameter  $d_{\text{pol}}$  of the soil polygons is a function of depth with its minimum value at the soil surface where macropore density is maximal and consequently distances between macropores are relatively small, and its maximum value deeper in the profile where macropore density is minimal.  $d_{\text{pol}}$  as a function of depth is determined from a maximum  $d_{\text{p,max}}$  and minimum  $d_{\text{p,min}}$  polygon diameter, both input parameters, and the relative macropore density  $M$  (-) as a function of depth according to:

$$d_{\text{pol}} = d_{\text{p,min}} + (d_{\text{p,max}} - d_{\text{p,min}})(1 - M) \quad (6.23.a)$$

where  $M$  depends on the static macropore volume if present:

$$M = \frac{V_{st}}{V_{st,0}} \quad \text{for } V_{st,0} > 0 \quad (6.23.b)$$

If no static macropore volume is present  $M$  depends on the volumetric proportion of the IC domain:

$$M = \frac{P_{ic}}{P_{ic,0}} \quad \text{for } V_{st,0} = 0 \quad \text{and } P_{ic,0} > 0 \quad (6.23.c)$$

If no static macropore volume and no IC domain are present,  $M$  can be defined as a function of depth with  $Z_{dpmax}$  as the depth below which  $d_{pol}$  equals  $d_{p,max}$ :

$$M = \max\left(0, 1 - \frac{z}{Z_{dpmax}}\right) \quad \text{for } V_{st,0} = 0 \quad \text{and } P_{ic,0} = 0 \quad (6.23.d)$$

### 6.1.2 Water flow and balance

In SWAP macropore water flow and balance comprise (Figure 6.5):

1. storage of water in the macropore domains  $S_{mp}$  (cm);
2. infiltration of water into macropores at soil surface, by precipitation, irrigation and snowmelt water falling directly into macropores  $I_{pr}$  and by overland flow (runoff) into the macropores  $I_{ru}$  (cm d<sup>-1</sup>);
3. lateral infiltration into the unsaturated soil matrix  $q_{lu}$  (cm d<sup>-1</sup>);
4. lateral infiltration into and exfiltration out of the saturated soil matrix  $q_{ls}$  (cm d<sup>-1</sup>);
5. lateral exfiltration out of the saturated soil matrix by interflow out of a zone with perched groundwater  $q_{li}$  (cm d<sup>-1</sup>);
6. rapid drainage to drainage systems  $q_{rd}$  (cm d<sup>-1</sup>).

**Figure 6.5** Schematic representation of the soil profile with soil matrix, drain, groundwater, perched groundwater (p.g.), macropores in MB and IC domains, and the various macropore water balance terms. Mark that the saturated lateral exchange flux  $q_{ls}$  can occur in two directions. See text for explanation of terms.

### Water balance

The water balance of the MB domain for a given time interval  $dt = t_0 \rightarrow t$  reads:

$$S_{mb}^t - S_{mb}^{t_0} = \int_{t_0}^t (I_{pr,mb} + I_{ru,mb} + q_{li,mb} - q_{lu,mb} - q_{ls,mb} - q_{rd}) dt \quad (6.24.a)$$

where:

$$q_{li,mb} = \int_{z_{if,bot}}^{z_{if,top}} q_{li,mb}^* dz; \quad q_{lu,mb} = \int_{z_{uns,bot}}^{z=0} q_{lu,mb}^* dz; \quad q_{ls,mb} = \int_{z_{prof,bot}}^{z_{uns,bot}} q_{ls,mb}^* dz \quad (6.24.b)$$

All balance terms are positive except  $q_{ls}$  which is positive in case of infiltration into the matrix and negative in case of exfiltration out of the matrix. The storage term is always less than or equal to the actual macropore volume. All flux densities  $q^*$  are defined per unit of depth ( $\text{cm cm}^{-1} \text{d}^{-1}$ ). Depths  $z_{if,top}$ ,  $z_{if,bot}$ ,  $z_{uns,bot}$  and  $z_{prof,bot}$  (cm) refer to top and bottom of interflow zone, and bottom of unsaturated zone and soil profile, respectively.

The water balance calculation of the IC domain is equal to that of the MB domain with the exception of the rapid drainage term. Per definition, rapid drainage occurs exclusively in the MB domain.

### Inflow at soil surface ( $I_{pr}$ and $I_{ru}$ )

The rate  $I_{pr}$  of precipitation, irrigation and snowmelt water routed directly into the macropores at the soil surface at a given precipitation/irrigation/snowmelt intensity  $P$  ( $\text{cm d}^{-1}$ ) is calculated as:

$$I_{pr} = A_{mp} P \quad (6.25)$$

where  $A_{mp}$  ( $\text{cm}^2 \text{cm}^{-2}$ ) is the horizontal macropore area fraction at the soil surface which equals  $V_{mp,0}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) the total macropore volume fraction at soil surface. For macropore domain  $dm$  (subscript  $dm = mb$  or  $ic$ ) this direct infiltration reads:

$$I_{pr,dm} = A_{dm} P \quad \text{with} \quad A_{dm} = P_{dm,0} V_{mp,0} \quad (6.26)$$

where  $P_{dm,0}$  (-) is the volumetric proportion of domain  $dm$  at the soil surface. In case of a snowpack on top of the soil surface, it is assumed that the macropores are sealed off from the atmosphere and consequently  $I_{pr} = 0$ , except when snowmelt occurs.

Infiltration rate term  $I_{ru}$  occurs when the head boundary condition holds for the top boundary of the soil matrix (see Section 2.7.3.1). In that case the water balance of the ponding layer is calculated, which includes  $I_{ru}$ . Ponding occurs when the total of precipitation, irrigation, snow melt, runoff and inundation intensity exceeds soil matrix infiltration capacity. Runoff into the macropores is described in the same form as used for regular runoff to surface water or adjacent fields (Section 4.1) to allow for similar incorporation into the numerical solution of the top boundary (Appendix 17):

$$I_{ru} = \frac{h_0}{\gamma_{Iru}} \quad (6.27)$$

where  $h_0$  (cm) is the pressure head at the soil surface that equals the ponding height and  $\gamma_{Iru}$  (d) is the resistance for macropore inflow at the soil surface. The macropore inflow resistance is estimated from the maximum ponding height  $h_{0,max}$  assuming no runoff, either into macropores or regular, and the vertical hydraulic conductivity of the macropores at soil surface  $K_{ver,mp}$  ( $\text{cm d}^{-1}$ ). The latter is derived as a function of effective macropore width at soil surface from a theoretical slit model presented by Bouma and Anderson (1973):

$$\gamma_{Iru} = \frac{h_{0,max}}{k_{ver,mp}} \quad \text{with} \quad K_{ver,mp} = 14.4 \cdot 10^8 \frac{w_{mp,0}^3}{d_{pol,0}} \quad (6.28)$$

It can be seen that even the lower limit of macropore width (100  $\mu\text{m}$ ) yields large conductivities in the order of 100-1000 ( $\text{cm d}^{-1}$ ) and consequently very low inflow resistances of 0.001-0.01 d. This implies that ponding water is routed preferentially into macropores. To account for the micro relief at the soil surface, mostly a threshold value for ponding height is used that must be exceeded before regular

runoff starts. It is assumed that this does not apply to runoff into macropores, because it is very likely that micro depressions at the soil surface are connected to macropores. As a consequence, runoff into macropores is favoured over regular runoff and thus  $\gamma_{Iru}$  is not a very sensitive variable.

Distribution of  $I_{ru}$  over MB and IC domains is according to their proportions at the soil surface  $P_{mb,0}$  and  $P_{ic,0}$ .

#### Lateral infiltration into the unsaturated matrix $q_{lu}$

Lateral infiltration of macropore water into the unsaturated soil matrix takes place strictly over the depth where stored macropore water is in contact with the unsaturated matrix. Two lateral infiltration mechanisms are relevant: absorption of macropore water when capillary forces dominate and Darcy flow due to a pressure head gradient from macropore wall to centre of the effective matrix polygon. Absorption is the dominant mechanism at low soil moisture contents. It will be negligible under wet conditions even when there is a large pressure head gradient. In the latter case Darcy flow will be dominant. Darcy flow is very small under dry conditions because of very low hydraulic conductivities. Therefore, for each situation the flow rates of both infiltration mechanisms are calculated and the unsaturated infiltration flux is set equal to the largest of these two rates.

Lateral absorption is described with Philip's sorptivity (Philip, 1957):

$$I_{ab,t}^* = A_{wall,mtx}^* S_p \sqrt{t - t_0} = \frac{4S_p \sqrt{t - t_0}}{d_{pol} \sqrt{1 - V_{mp}}} \quad (6.29)$$

where  $I_{ab,t}^*$  is the lateral absorption per unit of depth ( $\text{cm cm}^{-1}$ ) over time interval  $t_0 \rightarrow t$  (d) and  $S_p$  is Philip's sorptivity ( $\text{cm d}^{-0.5}$ ). The meaning of  $A_{wall,mtx}^*$  is explained in Appendix 2 (Eq.(A2.12)).  $S_p$  is a function of initial volumetric moisture content  $\theta_0$  ( $\text{cm}^3 \text{cm}^{-3}$ ) at  $t = t_0$ , the time of first contact of macropore water with the matrix. It is empirically described as (adapted from Greco et al., 1996):

$$S_p = S_{p,max} \left( 1 - \frac{\theta_0 - \theta_r}{\theta_s - \theta_r} \right)^{\alpha_s} = S_{p,max} \left( \frac{\theta_s - \theta_0}{\theta_s - \theta_r} \right)^{\alpha_s} \quad (6.30)$$

where  $S_{p,max}$  is the maximum sorptivity when  $\theta_0 = \theta_r$  (residual moisture content) and  $\alpha_s$  is a fitting parameter (-).

Average, constant absorption rate  $q_{lu,ab}^*$  per unit of depth ( $\text{cm cm}^{-1} \text{d}^{-1}$ ) for time interval  $t_1 \rightarrow t_2$  is obtained from:

$$q_{lu,ab}^* = \frac{I_{ab,t_2}^* - I_{ab,t_1}^*}{t_2 - t_1} \quad (6.31)$$

Infiltration rate by Darcy flow per unit of depth  $q_{lu,D}^*$  ( $\text{cm cm}^{-1} \text{d}^{-1}$ ) reads:

$$q_{lu,D}^* = f_{shp} A_{wall}^* K_h \frac{(h_{mp} - h_{mt})}{x_{pol}} = \frac{f_{shp} 8K_h (h_{mp} - h_{mt})}{d_{pol}^2} \quad (6.32)$$

where  $K_h$  ( $\text{cm d}^{-1}$ ) is the hydraulic conductivity as a function of pressure head in the unsaturated matrix  $h_{mt}$  (cm) and term  $(h_{mp} - h_{mt}) / x_{pol}$  is the lateral pressure head gradient between macropore and centre of the matrix polygon. Parameter  $f_{shp}$  (-) is a shape factor to account for the uncertainties in the theoretical description of lateral infiltration by Darcy flow originating from uncertainties in the exact shape of the soil matrix polygons. Depending on whether the polygons are more plate or cylinder shaped, the figure in Eq. (6.32) should be somewhere between 8 and 16. Thus, theoretically, the value of  $f_{shp}$  lies between 1 and 2. Pressure head  $h_{mp}$  as a function of depth is obtained from the macropore water level elevation  $\phi_{mp}$  and depth  $z$  as:

$$h_{mp} = \phi_{mp} - z \quad (6.33)$$

Finally, the lateral infiltration fluxdensity into the unsaturated matrix per unit of depth  $q_{lu}^*$  (cm cm<sup>-1</sup> d<sup>-1</sup>) is obtained by taking the largest flow rate:

$$q_{lu}^* = \max\left(q_{lu,ab}^*, q_{lu,D}^*\right) \quad (6.34)$$

Distribution of  $q_{lu}^*$  over MB and IC domains is according to their proportions  $P_{mb}$  and  $P_{ic}$  at the specific depth  $z$ .

*Lateral infiltration into and exfiltration out of the saturated matrix  $q_{ls}$*

Lateral infiltration of macropore water into the saturated soil matrix and lateral exfiltration of soil matrix water into the macropores takes place strictly over the depth where stored macropore water is in contact with the saturated matrix. This only concerns static macropores below the groundwater table, since in the present concept in saturated condition the soil is assumed swollen to its maximum volume, without dynamic macropore volume.

The lateral in- and exfiltration rate per unit of depth  $q_{ls,D}^*$  (cm cm<sup>-1</sup> d<sup>-1</sup>) in case of water filled macropores ( $h_{mp} > 0$ ) is described by Darcy flow similar to Eq. (6.32):

$$q_{ls,D}^* = f_{shp} A_{wall}^* K_{sat} \frac{(h_{mp} - h_{mt})}{x_{pol}} = \frac{f_{shp} 8K_{sat} (h_{mp} - h_{mt})}{d_{pol}^2} \quad (6.35)$$

The same shape factor  $f_{shp}$  as in Eq. (6.32) is adopted since the same considerations about uncertainties in the exact shape of the soil matrix polygons apply. Infiltration occurs if  $h_{mp} > h_{mt}$  and exfiltration if  $h_{mp} < h_{mt}$ .

Exfiltration rate out of the matrix into empty macropores ( $h_{mp} = 0$ ) is described as a seepage face:  $q_{ls,seep}^*$  (cm cm<sup>-1</sup> d<sup>-1</sup>). It is approached with a seepage resistance  $\gamma_{seep}$  (d) that is based on Ernst's drainage resistance equation Eq. (4.16) without term  $\gamma_{entr}$ :

$$q_{ls,seep}^* = -\frac{h_{mt}}{\gamma_{seep}} = -\frac{h_{mt}}{\gamma_{ver} + \gamma_{hor} + \gamma_{rad}} \quad (6.36.a)$$

$$\gamma_{ver} = \frac{D_{seep}}{K_{sat}} \quad \text{with } D_{seep} = \phi_{gwl} - z_{seep} \quad (6.36.b)$$

$$\gamma_{hor} = \frac{d_{pol}^2}{8K_{sat} D_{seep}} \quad (6.36.c)$$

$$\gamma_{rad} = \frac{d_{pol}}{\pi K_{sat}} \ln\left(\frac{D_{seep}}{u_{seep}}\right) \quad (6.36.d)$$

where  $\phi_{gwl}$  (cm) is the groundwater elevation,  $z_{seep}$  (cm) is bottom of seepage layer which equals depth of either bottom of macropores or macropore water level,  $D_{seep}$  (cm) is thickness of seepage zone and  $u_{seep}$  (cm) is thickness of seepage face which is set to 10% of  $D_{seep}$ . Eq. (6.36.b)-Eq. (6.36.d) are derived from Eq. (4.20)-Eq. (4.22).

Distribution of  $q_{li}^*$  over MB and IC domains is according to their proportions  $P_{mb}$  and  $P_{ic}$  at the specific depth  $z$ .

*Lateral exfiltration out of the saturated matrix as interflow  $q_{li}$*

Lateral exfiltration  $q_{li}^*$  (cm cm<sup>-1</sup> d<sup>-1</sup>) out of the saturated soil matrix into macropores by interflow (Section 4.2) out of a zone with perched groundwater occurs over the depth of perched groundwater. This process is a special case of exfiltration of soil water from the saturated zone into the macropores and is described in a similar way using Eq. (6.35) and Eq. (6.36), but with an opposite sign due to its definition in Eq. (6.24). If  $h_{mp} > h_{mt}$ , infiltration into the saturated matrix in the perched groundwater zone occurs according to Eq. (6.35). A perched groundwater zone is here defined as a saturated zone

above groundwater level that is separated from the saturated zone below groundwater level by an unsaturated zone which contains at least a critical value  $V_{\text{undsat,crit}}$  (default: 0.1 cm) of under-saturated volume  $V_{\text{undsat}} (= \int [\theta_s - \theta] dz \text{ cm})$ .

Distribution of  $q_{\text{li}}^*$  over the MB and IC domains is according to their proportions  $P_{\text{mb}}$  and  $P_{\text{ic}}$  at the specific depth  $z$ .

#### Rapid drainage $q_{\text{rd}}$

Rapid drainage to drainage systems can occur via a network of lateral interconnected cracks or via otherwise (nearly) interconnected macropores. Also when macropores are separated by just thin walls of soil matrix they can enhance drainage considerably. Fed by macropore water, the small matrix barriers will become saturated even when the soil matrix as a whole remains unsaturated. They then form part of a saturated macropore-soil-matrix-system that conducts water better in vertical and horizontal direction than the bulk of the soil matrix (Nieber et al., 2006). Sidle et al. (2001) proposed the concept of a self-organising network of preferential flow pathways, where the connections in the network are controlled by moisture level.

In SWAP, the complex process of rapid drainage is described with a drainage resistance. This resistance may depend on the width of macropores and of shrinkage cracks in particular: wider cracks have higher hydraulic conductivities. It may also depend on macropore water level: the higher this level, the more macropore volume involved, the higher the hydraulic conductivity and the lower the resistance. Therefore, the functional input parameter 'drainage resistance' is considered as a reference drainage resistance: it is valid for a defined reference situation. The actual drainage resistance is derived from the reference resistance according to the deviations from the actual situation to the reference situation.

The reference situation is preferably an average situation at the field scale and should be based on a relevant reference level. In this SWAP version it is fixed. The reference level is chosen to be the drainage basis: drain depth or surface water level. The definition of the reference situation is: soil moisture is in hydrostatic equilibrium with groundwater level at depth of drainage basis and with the water level in the MB macropores at a depth of three-quarters of the drainage basis depth.

The actual drainage resistance  $\gamma_{\text{act}} (d)$  is calculated from the reference drainage resistance  $\gamma_{\text{ref}} (d)$  according to the ratio between actual and reference transmissivity  $KD$  of the MB macropores ( $\text{cm}^2 d^{-1}$ ):

$$\gamma_{\text{act}} = \frac{[KD]_{\text{act}}}{[KD]_{\text{ref}}} \gamma_{\text{ref}} \quad (6.37.a)$$

where:

$$[KD] = \int_{z_{\text{botMB}}}^{z_{\text{levMB}}} K_{\text{lat}} dz = \int_{z_{\text{botMB}}}^{z_{\text{levMB}}} C \frac{w_{\text{cr}}^{r_{\text{rd}}}}{d_{\text{pol}}} dz = C \int_{z_{\text{botMB}}}^{z_{\text{levMB}}} \frac{w_{\text{cr}}^{r_{\text{rd}}}}{d_{\text{pol}}} dz \quad (6.37.b)$$

with  $K_{\text{lat}}$  ( $\text{cm d}^{-1}$ ) the lateral hydraulic conductivity of the macropores,  $z_{\text{botMB}}$  and  $z_{\text{levMB}}$  (cm) the depths of the bottom of and the water level in the MB macropores.  $C$  is a constant that follows from the slit model for conductivity (Eq. (6.28)). Its value is irrelevant because it is eliminated in Eq. (6.37.a). The exponent  $r_{\text{rd}} (-)$  is a reaction coefficient that determines the effect of width  $w_{\text{cr}}$  (cm) on  $\gamma_{\text{act}}$ . It varies between 0 and 3. When  $r_{\text{rd}} = 0$ ,  $\gamma_{\text{act}}$  becomes independent of  $w_{\text{cr}}$ .

Rapid drainage flux  $q_{\text{rd}}$  ( $\text{cm d}^{-1}$ ) is calculated from MB domain water level elevation  $\phi_{\text{MB}}$  (cm) above drainage level  $\phi_{\text{db}}$  (cm) and  $\gamma_{\text{act}}$  ( $d^{-1}$ ) at actual moisture content:

$$q_{\text{rd}} = \frac{\phi_{\text{MB}} - \phi_{\text{db}}}{\gamma_{\text{act}}} \quad (6.38)$$

## 6.2 Numerical implementation

SWAP applies the same vertical spatial ( $\Delta z$ ) and temporal ( $\Delta t$ ) discretisation for macropore flow as is used for matrix flow. Besides, SWAP uses a horizontal discretisation in the form of macropore domains for macropore flow. In this section the horizontal discretisation, its relationship with vertical and temporal discretisation, and the numerical implementation of water balance and flow equations are described.

### 6.2.1 Macropore geometry

#### 6.2.1.1 Continuity

To obtain the required resolution in IC macropores, the IC domain is divided into  $n_{sd}$  sub-domains. This partition represents the horizontal discretisation of the macropore system. The IC volume at soil surface, minus the  $R_{ZAh}$ -volume, is equally distributed over the  $n_{sd}$  sub-domains. Thus, all  $n_{sd}$  sub-domains take up an equal amount of infiltrating water at the soil surface. The volumetric proportion  $P_{sd,j}$  of sub-domain  $j$  as a function of  $z$  is calculated according to:

$$P_{sd,j} = \frac{1}{\frac{1}{P_{ic,0}} + F - 1} \frac{1 - R_{ZAh}}{n_{sd}} \quad \text{for } 0 \geq z > z_{sd,j+1} \quad (6.39.a)$$

$$P_{sd,j} = \frac{\left( F - \frac{j-1}{n_{sd}} (1 - R_{ZAh}) \right)}{\frac{1}{P_{ic,0}} + F - 1} \quad \text{for } z_{sd,j+1} \geq z > z_{sd,j} \quad (6.39.b)$$

$$P_{sd,j} = 0 \quad \text{for } z \leq z_{sd,j} \quad (6.39.c)$$

where  $j = 1$  is the deepest and  $j = n_{sd}$  the shallowest sub-domain (respectively left and right in Figure 6.1.B), and  $z_{sd,j}$  is the depth at which sub-domain  $j$  ends:

$$z_{sd,j} = Z_{Ah} - (Z_{Ah} - Z_{ic}) \left( 1 - \frac{j-1}{n_{sd}} \right)^{\frac{1}{m}} \quad (6.40)$$

If option  $R_{ZAh} > 0$  is chosen, an extra  $Ah$ -sub-domain  $j = n_{sd} + 1$  is created with proportion:

$$P_{sd,n_{sd}+1} = \frac{R_{ZAh} + F - 1}{\frac{1}{P_{ic,0}} + F - 1} \quad \text{for } 0 \geq z > Z_{Ah} \quad (6.41.a)$$

$$P_{sd,n_{sd}+1} = 0 \quad \text{for } z \leq Z_{Ah} \quad (6.41.b)$$

Because the MB domain is always present, though sometimes with very low proportion, the total number of domains  $n_{dm} = n_{sd} + 1$ . In case of  $R_{ZAh} > 0$ ,  $n_{dm} = n_{sd} + 2$ . All domains are numbered from  $j = 1$  to  $n_{dm}$  with the MB domain being the first domain  $j = 1$  and the deepest IC domain the second  $j = 2$ .

In the model, the vertical coordinate  $z$  is partitioned into discrete model compartments  $i$  with thickness  $\Delta z_i$  (cm) between  $z_{b,i}$  and  $z_{t,i}$  at the bottom and top of the compartment, respectively. For each compartment a discrete macropore volume per domain is required. Volumetric proportion  $P_{j,i}$  for each combination of domain  $j$  and compartment  $i$  is obtained by integration of  $P_{MB}$  and  $P_{sd,j}$  as a function of  $z$  over the compartment thickness and dividing by  $\Delta z_i$ :

$$P_{1,i} = \frac{\int_{z_{b,i}}^{z_{t,i}} P_{MB} dz}{\Delta z_i} \quad \text{and} \quad P_{j,i} = \frac{\int_{z_{b,i}}^{z_{t,i}} P_{sd,j-1} dz}{\Delta z_i} \quad \text{for } 2 \leq j \leq n_{dm} \quad (6.42)$$

Per domain the macropore volume is vertically interconnected over the soil compartments. Domains  $j > 1$  to  $j + n_{dl,j}$  inclusive, that end in the same model compartment, are functionally equal and therefore are lumped for all compartments  $i = 1$  to  $ndb_j$  (compartment number that contains bottom of domain  $j$ ):

$$P_{j,i} = P_{j,i} + \sum_{l=1}^{n_{dl,j}} P_{j+l,i} \quad \text{and} \quad P_{l,i} = P_{l+n_{dl,j},i} \quad \text{for all } l: j+1 \leq l \leq n_{dm} - n_{dl,j} \quad (6.43)$$

For each lumped domain  $n_{dm}$  is reduced with 1. In this way, the resolution of the horizontal discretisation in terms of  $n_{dm}$  is determined by  $n_{sd}$ , the thickness of compartments and the shape of curve  $F$ : the combination of large  $n_{sd}$ , small  $\Delta z$ 's in the IC domain and a linear  $F$ -curve ( $m = 1$ ) yields the largest  $n_{dm}$ .

### 6.2.1.2 Persistency

The volume of macropores  $V_{mp,j,i}$  ( $\text{cm}^3 \text{ cm}^{-2}$  unit of area) for domain  $j$  in compartment  $i$  is calculated for each time-step  $\Delta t$  as:

$$V_{mp,j,i} = P_{j,i} (V_{st,i} + V_{dy,i}) \quad (6.44)$$

Static  $V_{st,i}$  and dynamic  $V_{dy,i}$  macropore volume ( $\text{cm}^3 \text{ cm}^{-2}$ ) in each compartment  $i$  are obtained as explained below. Dynamic volume is changing in time, static volume is not. Consequently, if dynamic volume is present in compartment  $i$ , the total macropore volume in this compartment is changing in time as well.

The total volume  $V_{dm,j}$  ( $\text{cm}^3 \text{ cm}^{-2}$ ) of macropore domain  $j$  equals:

$$V_{dm,j} = \sum_{i=1}^{ndb_j} V_{mp,j,i} \quad (6.45)$$

where  $ndb_j$  is the number of the compartment that contains the bottom of domain  $j$ .

#### Static macropore volume

The volumes of static macropores per compartment  $i$  for the MB and IC domain,  $V_{st,mb,i}$  and  $V_{st,ic,i}$  ( $\text{cm}^3 \text{ cm}^{-2}$ ), are obtained by integration over  $\Delta z_i$ :

$$V_{st,mb,i} = \int_{z_{b,i}}^{z_{t,i}} V_{st,mb} dz \quad \text{and} \quad V_{st,ic,i} = \int_{z_{b,i}}^{z_{t,i}} V_{st,ic} dz \quad (6.46)$$

The total volume of static macropores  $V_{st,i}$  in compartment  $i$  equals:

$$V_{st,i} = V_{st,mb,i} + V_{st,ic,i} \quad (6.47)$$

#### Dynamic macropore volume

Dynamic macropore volume  $V_{dy,i}$  ( $\text{cm}^3 \text{ cm}^{-2}$ ) in compartment  $i$  is computed for each time-step  $\Delta t$  by substituting Eq. (6.13) in Eq. (6.12) and multiplying with compartment thickness  $\Delta z_i$ :

$$V_{dy,i} = \left( 1 - \frac{V_{st,i}}{\Delta z_i} \right) \frac{V_{sh,i} + \left( 1 - V_{sh,i} \right)^{\frac{1}{s_i}} - 1}{\left( 1 - V_{sh,i} \right)^{\frac{1}{s_i}}} \Delta z_i \quad (6.48)$$

The shrinkage volume fraction  $V_{sh,i}$  ( $\text{cm}^3 \text{ cm}^{-3}$ ) is calculated from actual moisture content and shrinkage characteristic of compartment  $i$  at the beginning of  $\Delta t$ :

$$V_{sh,i} = (e_{s,i} - e_i) V_{sol,i} \quad (6.49.a)$$

where:

$$e_i = f(\vartheta_i)_i, \quad \vartheta_i = \frac{\theta_i}{V_{sol,i}}, \quad e_{s,i} = \vartheta_{s,i} = \frac{\theta_{s,i}}{V_{sol,i}} \quad \text{and} \quad V_{sol,i} = 1 - \theta_{s,i} \quad (6.49.b)$$

with  $\theta_i$  is the actual and  $\theta_{s,i}$  the saturated volumetric moisture content ( $\text{cm}^3 \text{cm}^{-3}$ ) of compartment  $i$ .

In order to correctly model infiltration into the soil matrix at soil surface, thin model compartments in the order of 1 cm thick are advised for the top of the soil profile (Van Dam and Feddes, 2000). Because of the dynamical conditions at soil surface and the small storage capacity of the thin compartments, moisture contents may change rapidly. As a result shrinkage volume at soil surface may appear and disappear faster than in reality. Because the quantity of shrinkage volume at the soil surface is crucial for determining the amount of precipitation water infiltrating into the macropores, shrinkage volume of the first compartments is calculated on the basis of moisture content of the compartment that contains a reference depth  $z_{crack}$ , where moisture conditions are less dynamical.  $z_{crack}$  is an input parameter.

### 6.2.1.3 Horizontal distribution

Effective diameter of soil polygons  $d_{pol,i}$  (cm) for compartment  $i$  is calculated with Eq. (6.23) by substituting  $V_{st,i}$ ,  $1 - P_{1,i}$  and  $z_i$  for  $V_{st}$ ,  $P_{1c}$  and  $z$ , respectively.  $z_i$  (cm) is the depth of node  $i$  which is in the middle of compartment  $i$ .

The effective vertical area of macropore walls per unit of horizontal area  $A_{wall,i}$  ( $\text{cm}^2 \text{cm}^{-2}$ ) is obtained by multiplying the vertical area of macropore walls per unit of volume  $A_{wall,i}^*$  with compartment thickness  $\Delta z_i$ :

$$A_{wall,i} = A_{wall,i}^* \Delta z_i = \frac{4}{d_{pol,i}} \Delta z_i \quad (6.50)$$

The effective horizontal distance  $x_{pol,i}$  (cm) is calculated with Eq. (6.21) by substituting  $d_{pol,i}$  for  $d_{pol}$ . The effective crack width  $w_{cr,i}$  (cm) in the MB domain for compartment  $i$  is calculated from Eq. (6.22) as:

$$w_{cr,i} = d_{pol,i} \left( 1 - \sqrt{1 - \frac{V_{mp,1,i}}{\Delta z_i}} \right) \quad (6.51)$$

## 6.2.2 Water flow and balance

The water balance of macropore domain  $j = 1$  (MB domain) for time-step  $\Delta t$  (d) reads in accordance with Eq. (6.24):

$$S_j^t - S_j^{t-\Delta t} = \left( I_{pr,j} + I_{ru,j} + \sum_{i=nit}^{nib} q_{li,j,i} \Delta z_i - \sum_{i=1}^{nub} q_{lu,j,i} \Delta z_i - \sum_{i=nub+1}^{ndb_j} q_{ls,j,i} \Delta z_i - q_{rd} \right) \Delta t \quad (6.52)$$

Water balance equations of all other domains  $j > 1$  are equal to Eq. (6.52) but with exclusion of the rapid drainage term  $q_{rd}$  that only applies to domain 1, the MB domain. The compartment numbers  $nit$ ,  $nib$ ,  $nub$  and  $ndb_j$  refer to the top and bottom compartment with interflow from perched groundwater, the bottom (deepest) unsaturated compartment and the compartment with bottom of domain  $j$ , respectively. Storage  $S_j$  is always limited to  $0 \leq S_j \leq V_{dm,j}$ . In case of water deficit ( $S_j < 0$ ) all outgoing fluxes are decreased with a part of the deficit according to their relative rate. In case of water excess ( $S_j > V_{dm,j}$ ) all incoming fluxes are decreased with a part of the excess according to their relative rate. The excess of the inflow at soil surface is distributed over macropore domains that are not fully filled up, that is, if  $S < V_{dm}$  for a particular domain. The remaining excess is added to the ponding layer.

### Inflow at soil surface ( $I_{pr}$ and $I_{ru}$ )

The inflow at the soil surface fluxes  $I_{pr}$  and  $I_{ru}$  (cm d<sup>-1</sup>) are calculated according to Eq. (6.25) to (6.28) with the relevant properties of the first compartment. When these fluxes exceed storage capacity of total macropore volume, the inflow excess is added to the ponding layer before calculation of regular runoff takes place.

Distribution of  $I_{pr}$  and  $I_{ru}$  over all macropore domains  $j$  is according to the domains proportions at soil surface, that is, in model compartment 1:

$$I_{pr,j} = P_{j,1} I_{pr} \quad \text{and} \quad I_{ru,j} = P_{j,1} I_{ru} \quad (6.53)$$

### Lateral infiltration into the unsaturated matrix $q_{lu}$

Cumulative lateral absorption  $I_{ab,j,i}$  (cm) for all compartments  $i$  of the unsaturated matrix that are in contact with water in macropore domain  $j$  is computed according to Eq. (6.29):

$$I_{ab,j,i} = P_{j,i} A_{wall,mtx,i} S_{p,j,i} \sqrt{t_{cum,j,i}} = P_{j,i} \frac{4\Delta z_i S_{p,j,i} \sqrt{t_{cum,j,i}}}{d_{pol,i} \sqrt{1 - \frac{(V_{dy,i} + V_{st,i})}{\Delta z_i}}} \quad (6.54)$$

where  $t_{cum,j,i}$  (d) is the cumulative time since first contact of compartment  $i$  with water in macropore domain  $j$ . At each new contact event,  $S_{p,j,i}$  and  $t_{cum,j,i}$  are updated.

The sorptivity approach assumes that the moisture content is not influenced by another process than sorption. In the model, moisture content  $\theta_i$  is also affected by vertical matrix flow and uptake by roots. To account for this inadequacy, for each time-step sorptivity  $S_{p,j,i}$  is corrected according to the deviation  $\Delta\theta_i$  between actual  $\theta_i$  and theoretical  $\theta_{the,j,i}$  moisture content at the beginning of the time-step:

$$S_{p,j,i} = S_{p,max,i} \left( \frac{\theta_{s,i} - \theta_{0,j,i} - \Delta\theta_{j,i}}{\theta_{s,i} - \theta_{r,i}} \right)^{\alpha_{s,i}} \quad (6.55)$$

where  $\Delta\theta_{j,i} = \theta_i - \theta_{the,j,i}$ . For further explanation, see Eq. (6.30).  $\theta_{the,j,i}$  is computed with Eq. (6.54) on the basis of initial sorptivity  $S_{p,j,i}$  that is obtained by Eq. (6.55) without term  $\Delta\theta_{j,i}$ .

The lateral absorption rate during time step  $\Delta t$  is linearised to obtain an average, constant rate  $q_{lu,ab,j,i}$  (cm d<sup>-1</sup>):

$$q_{lu,ab,j,i} = \frac{I_{ab,j,i}^t - I_{ab,j,i}^{t-\Delta t}}{\Delta t} \quad (6.56)$$

Infiltration rate  $q_{lu,D,j,i}$  (cm d<sup>-1</sup>) by lateral Darcy flow from domain  $j$  into compartment  $i$  reads in accordance to Eq. (6.32):

$$q_{lu,D,j,i} = P_{j,i} f_{shp} A_{wall,i} K_{h,i} \frac{(h_{mp,j,i} - h_{mt,i})}{x_{pol,i}} = P_{j,i} \frac{f_{shp} 8K_{h,i} (h_{mp,j,i} - h_{mt,i})}{d_{pol,i}^2} \quad (6.57)$$

where  $h_{mp,j,i}$  is calculated with Eq. (6.33) by using  $\phi_{mp,j}$  (cm), the water level in domain  $j$ , and  $z_i$ .

The resulting lateral infiltration rate  $q_{lu,j,i}$  (cm d<sup>-1</sup>) from macropore domain  $j$  into unsaturated compartment  $i$  is derived from Eq. (6.34).

### Lateral infiltration into and exfiltration out of the saturated matrix $q_{ls}$

Rate of lateral water exchange  $q_{ls,j,i}$  (cm d<sup>-1</sup>) between macropore domain  $j$  and saturated compartment  $i$  by Darcy flow is computed in accordance to Eq. (6.35):

$$q_{ls,D,j,i} = P_{j,i} f_{shp} A_{wall,i} K_{sat,i} \frac{(h_{mp,j,i} - h_{mt,i})}{x_{pol,i}} = P_{j,i} \frac{f_{shp} 8K_{sat,i} (h_{mp,j,i} - h_{mt,i})}{d_{pol,i}^2} \quad (6.58)$$

and in case of a seepage face ( $h_{mp,j,t} = 0$ ) according to Eq. (6.36):

$$q_{ls,seep,j,i} = - \frac{h_{mt,i}}{\gamma_{ver,i} + \gamma_{hor,i} + \gamma_{rad,i}} \quad (6.59.a)$$

$$\gamma_{ver,i} = \frac{\Delta z_i}{K_{sat,i}} \quad (6.59.b)$$

$$\gamma_{hor,i} = \frac{d_{pol,i}^2}{8K_{sat,i}\Delta z_i} \quad (6.59.c)$$

$$\gamma_{rad,i} = \frac{d_{pol,i}}{\pi K_{sat,i}} \ln \left( \frac{\Delta z_i}{u_{seep,i}} \right) \quad (6.59.d)$$

where  $u_{seep,i}$  is set to 10% of  $\Delta z_i$ .

#### Lateral exfiltration out of the saturated matrix as interflow $q_{li}$

Lateral exfiltration rate  $q_{li,j,i}$  (cm d<sup>-1</sup>) out of compartment  $i$  with perched groundwater into macropore domain  $j$  by interflow is calculated according to Eq. (6.58) and Eq. (6.59) with an opposite sign.

#### Rapid drainage $q_{rd}$

The actual drainage resistance  $\gamma_{act}$  (d<sup>-1</sup>) for calculating rapid drainage flux  $q_{rd}$  (cm d<sup>-1</sup>) according to Eq. (6.30) is obtained by:

$$\gamma_{act} = \frac{\sum_{i=nl_{act}}^{nb_{act}} \frac{w_{cr,act,i}^{rd}}{d_{pol,i}} \Delta z_i}{\sum_{i=nl_{ref}}^{nb_{ref}} \frac{w_{cr,ref,i}^{rd}}{d_{pol,i}} \Delta z_i} \gamma_{ref} \quad (6.60)$$

where  $nl$  and  $nb$  are the numbers of the compartments with the water level and the bottom of the MB domain, respectively, for actual and reference situation.

For use in solute models, the rapid drainage flux  $q_{rd}$  is distributed over the compartments  $nl_{act}$  to  $nb_{act}$  according to their relative KD values:

$$q_{rd,i} = \frac{\frac{w_{cr,act,i}^{rd}}{d_{pol,i}} \Delta z_i}{\sum_{i=nl_{act}}^{nb_{act}} \frac{w_{cr,act,i}^{rd}}{d_{pol,i}} \Delta z_i} q_{rd} \quad (6.61)$$

#### Numerical solution

For the numerical solution of Richards equation (Par. 2.7.2) the partial derivative of the exchange between macropores and matrix to the pressure head must be added to the total partial derivative to the pressure head. For each compartment  $i$  the macropore contribution to this derivative is the sum of the derivatives of all  $n_{dm,i}$  macropore domains  $j$ :

$$\frac{\partial S_{m,i}^{l+1,p}}{\partial h_i^{l+1,p}} = \sum_{j=1}^{n_{dm,i}} \left( \frac{\partial S_{mj,i}^{l+1,p}}{\partial h_i^{l+1,p}} \right) \quad (6.62)$$

where  $l$  refers to the time level and  $p$  to the iteration round. For the Darcy flow and seepage face fluxes  $q_{lu,D}$ ,  $q_{ls}$  and  $q_{li}$  the derivative to the pressure head is calculated as:

$$\frac{\partial S_{mj,i}^{l+1,p}}{\partial h_i^{l+1,p}} = \left( - \frac{q_{lu,D}^{l+1,p} \text{ or } q_{ls,j,i}^{l+1,p}}{h_{mp,j,i}^l - h_{mt,i}^{l+1,p}} \right) \text{ and } \frac{\partial S_{mj,i}^{l+1,p}}{\partial h_i^{l+1,p}} = \left( - \frac{q_{li,j,i}^{l+1,p}}{h_{mp,j,i}^l - h_{mt,i}^{l+1,p}} \right) \quad (6.63)$$

For the absorption flux  $q_{lu,ab}$  the derivative to the pressure head is obtained by:

$$\frac{\partial S_{m,j,i}^{l+1,p}}{\partial h_i^{l+1,p}} = \left( -\alpha_{S,i} \frac{q_{lu,ab,j,i}}{(\theta_{s,i} + \theta_{thr,j,i} - \theta_{0,j,i} - \theta_i)} \frac{\partial \theta_i}{\partial h_i} \right)^{l+1,p} \quad (6.64)$$

where  $\frac{\partial \theta_i}{\partial h_i}$  is the differential water capacity (Section 2.2).

## 6.3 User instructions

### 6.3.1 General input parameters

The most important aspect of macropore flow is that precipitation water is routed into macropores at the soil surface. A relatively small part of precipitation enters the macropore volume directly. Inflow of precipitation excess via overland flow in case of precipitation intensity exceeding matrix infiltration rate is the dominant source of macropore inflow at soil surface. In order to describe these inflow processes accurately, realistic precipitation intensities and matrix infiltration rates should be simulated. The consequences of this for the SWAP parameterisation other than the macropore parameters, are discussed below.

#### *Rainfall option*

For realistic rainfall intensities, rainfall option SWRAIN 3 is preferred (Section 3.7.1). Less preferable are options 1 and 2. Option 0, daily rainfall sum, is not recommended. This option may seriously underestimate macropore inflow at soil surface because of far too small rainfall intensities.

#### *Vertical discretisation*

Realistic simulation of matrix infiltration at the soil surface requires thin compartments in the top of the profile in the order of 1 cm thick (Van Dam and Feddes, 2000). A typical vertical discretisation for a macroporous field soil could be: for the first 10-20 cm compartments of 1 cm thick, for the next 20-30 cm 2.5 cm thick, until the depth of the bottom of the IC domain maximal 5 cm thick, until the depth of the bottom of the static macropores 5 to maximal 10 cm thick and below this depth compartments of 10-25 cm thick.

#### *Soil hydraulic functions*

The hydraulic functions of the soil matrix should be used. This implies that the saturated volumetric moisture content is without the static macropore volume. And that the saturated hydraulic conductivity concerns a soil physical conductivity of the matrix rather than a hydrological conductivity of the soil. The air-entry-value option should be switched off, thus  $h_e = 0$  (see Sections 2.3 and 2.8.1).

#### *Time step*

It is recommended to take  $10^{-5}$  or  $10^{-6}$  (d) for the minimum time step and  $10^{-1}$  (d) or less for the maximum time-step.

#### *Output*

Macropore simulation provides the option of output of a macropore water balance in the file \*.BMA. For this option, switch SWBMA should have value 1 (see Box 1.4). Automatically generated are output files MacroGeom.csv and SoilShrinkChar.csv, which contain a tabular representation of the macropore geometry and the shrinkage characteristics as computed by the model on basis of the user's input.

### 6.3.2 Macropore input parameters

The typical macropore input parameters are discussed in this Section. They are listed in Boxes 6.1 (Section 6.3.2.1: Macropore geometry) and 6.2 (Section 6.3.2.2: Water flow). The presented values concern a field experiment on water, bromide tracer and pesticide transport in a tile-drained field on

clay soil (Scorza Júnior et al., 2004). The field was located in the riverine area in the central part of the Netherlands. The soil concerned light to moderate clay (30-55 mass-% clay) and the crop was winter wheat. At 320 cm depth the clay soil was underlain by a coarse sand aquifer. The presented values are the first results of a calibration of SWAP against the dataset.

### 6.3.2.1 Macropore geometry

The input parameters of the macropore geometry are listed in Box 6.1. They are discussed below.

**Figure 6.6** Fraction of functional IC macropores  $F$  as a function of depth is described by a power law function with power  $m$ .  $m = 1$  describes a linear decline, while  $m < 1$  represents shallow IC systems and  $m > 1$  deep IC systems.

#### Illustration of the effect of parameters on macropore geometry

Curve  $F$  in Figure 6.6 illustrates the effect of shape-factor  $m$  in combination with other macropore geometry parameters on the fraction of IC macropores that is functional at depth  $z$  (in case that  $R_{ZAH} = 0$ ). For  $m = 0.1, 0.4, 1.0, 2.5$  and  $10$ , respectively, depth  $z$  at which fraction  $F$  of functional IC macropores has declined to 0.5 equals  $-25.1, -35.6, -55, -70.5$  and  $-81$  cm, respectively. In general,  $m < 1$  describes shallow IC systems, while  $m > 1$  represents deep IC systems;  $m = 1$  describes an intermediate system with linear decline of functional IC macropores with depth. Optionally, two more shape parameters can be used to describe IC macropores in more detail. The symmetry-point-parameter SPOINT allows for 'standing' ( $m < 1$ ) and 'laying' ( $m > 1$ ) S-shaped  $F$ -curves. In combination with switch SWPOWM turned on, these curves can be modified into double convex ( $m < 1$ ) or double concave ( $m > 1$ ) curves (see Appendix 3 for examples). This allows for a functional description of macropore volume for a wide range of macropore geometries.

Default value of  $R_{ZAH}$  is 0.0. In Figure 6.2  $R_{ZAH} = 0.2$ , implying that at the bottom of the A-horizon ( $z = -25$  cm) 20% of the IC macropores has ended. If  $R_{ZAH} = 0$ , no IC macropores end above the bottom of the A-horizon. This option may be used to describe effects of tillage of the A-horizon. Data of a dye tracer experiment from Booltink (1993) for an A-horizon in a clay soil in Flevoland, the Netherlands, point out that this option may be relevant.

```

Figure 6.7 illustrates a macropore geometry with six domains: MB-domain, four IC sub-domains and Ah-sub-domain. In this example  $V_{st}$  at soil surface =  $0.04 \text{ cm}^3 \text{ cm}^{-3}$ ,  $P_{ic,0} = 0.6$ ,  $m = 0.4$ ,  $n_{dm} = 6$ ,  $n_{sd} = 4$ ,  $R_{ZAH} = 0.2$ ,  $Z_{AH} = -25 \text{ cm}$  and  $Z_{ic} = -85 \text{ cm}$ .  $V_{st,ic}$  at soil surface equals  $0.6 \times 0.04 = 0.024 \text{ cm}^3 \text{ cm}^{-3}$ . This volume is equally divided over the  $n_{sd} + 1$  sub-domains, including the Ah-sub-domain, because at soil surface  $P_{sd,j}$  is equal for all five sub-domains and amounts to  $0.6 / 5 = 0.12$ . Depth  $Z_{sd,j}$  of bottom of domains 2 to 6, equals  $-85$ ,  $-54.2$ ,  $-35.6$ ,  $-26.9$  and  $-25 \text{ cm}$ , respectively. Figure 6.8 presents an example of lumped sub-domains.

**Figure 6.7** Example of macropore geometry with the IC domain partitioned in four sub-domains and an Ah-sub-domain. Static macropore volume  $V_{st}$  (left) and volumetric proportion  $P$  (right) for MB, IC and IC-sub-domains.  $V_{st,0} = 0.04 \text{ cm}^3 \text{ cm}^{-3}$ ,  $P_{ic,0} = 0.6$ ,  $m = 0.4$ ,  $n_{dm} = 6$ ,  $n_{sd} = 4$ ,  $R_{ZAH} = 0.2$ ,  $Z_{AH} = -25 \text{ cm}$  and  $Z_{ic} = -85 \text{ cm}$ .  $z_{sd,j}$  is bottom of sub-domain  $j$ .

**Figure 6.8** Example of a combination of horizontal and vertical discretisation: number of IC sub-domains  $n_{sd} = 10$  (italic figures) while resulting total number of domains  $n_{dm} = 9$  (regular figures). Former sub-domains 3 and 4 are lumped to obtain present domain 4, and former sub-domains 6 and 7 are lumped to obtain present domain 6.  $V_{st,0} = 0.1 \text{ cm}^3 \text{ cm}^{-3}$ ,  $P_{ic,0} = 0.6$ ,  $m = 1$ ,  $R_{ZAH} = 0$ ,  $Z_{AH} = -20 \text{ cm}$ ,  $Z_{ic} = -80 \text{ cm}$ ,  $Z_{st} = -120 \text{ cm}$ .

#### Obtaining parameter values for macropore continuity and distribution

Most macropore input parameters are functional parameters with a physical relevancy. Information on their values can be derived from field and lab research. This especially counts for the depths  $Z_{Ah}$ ,  $Z_{ic}$  and  $Z_{st}$ . Depth of A-horizon  $Z_{Ah}$  may be known from soil mapping or field investigation.  $Z_{st}$  could be taken at or some decimetres above the mean annual lowest groundwater table. Processes leading to the presence of static macropores like ripening of clay and peat soils, and biological activities like soil penetration by plant roots, worms, insects and small mammals, will very likely be limited to this depth.  $Z_{ic}$  might be found at the depth of a clear shift in macropore density by investigation of a vertical soil profile in a pit or by taking relatively large soil samples (e.g. 20 cm diameter and 10-20 cm height).

Information about macropore volume to obtain a value for static macropore volume fraction at soil surface  $V_{st,0}$  (VIMpStSs in Box 6.1) and the distribution of macropore volume with depth, can be obtained by comparing pore volume of large samples with fitted values for  $\theta_{sat}$  of the original, unmodified Mualem-Van Genuchten functions. The latter expresses the pore volume of the soil matrix, while the first may comprise macropore volume as well.

Parameters which are relevant for the distribution of macropore volume with depth, PpIcSs, NumSbDm, PowM, DiPoMi, DiPoMa, and optional RZah, SPoint, SwPowM, ZDiPoMa, may be derived from inverse modelling of field experiments on tracer transport, with dye, conservative solutes or isotope tracers.

To illustrate the concept of the effective polygon diameter in case of combinations of cracks and hole-shaped macropores in the field, we consider the following equation:

$$d_{pol} = \frac{1}{\frac{1}{d_{pf}} + \pi \frac{(N_{h,1} d_{hf,1} + N_{h,2} d_{hf,2} + \dots)}{4A_h}} \quad (6.65)$$

where  $d_{pol}$  (cm) is the effective polygon diameter,  $d_{pf}$  (cm) is the actual average polygon diameter in the field,  $d_{hf,1}$  and  $d_{hf,2}$  (cm) are the diameters of two classes of hole-shaped macropores in the field and  $N_{h,1}$  and  $N_{h,2}$  are their numbers per area  $A_{hf}$  (cm<sup>2</sup>). If we assume that  $d_{pf} = 15$  cm, that there are two classes of hole-shaped parameters with an average diameter of 0.4 and 1.0 cm and with numbers per dm<sup>2</sup> of 3 and 1, then the effective polygon diameter will be 11.9 cm.

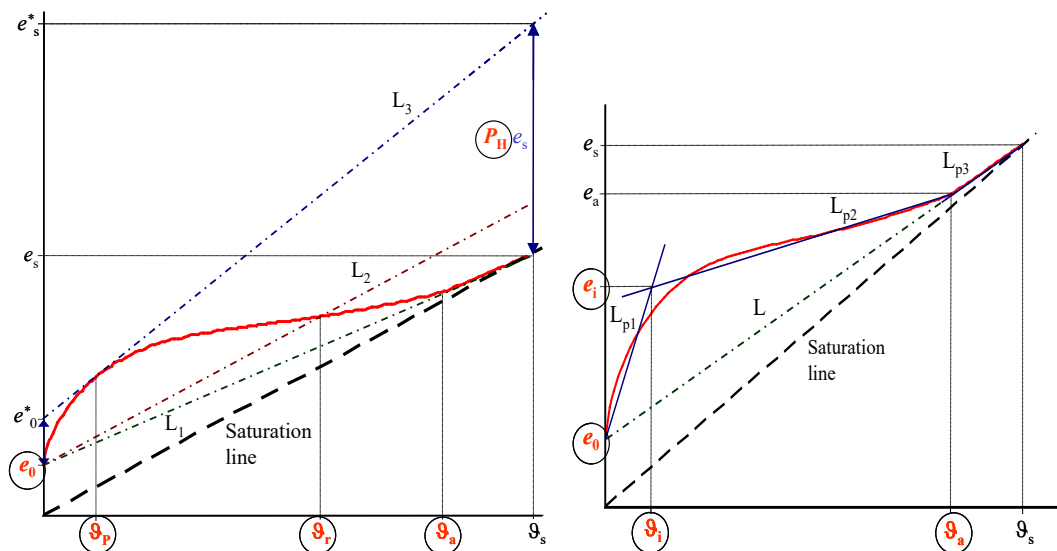

#### Shrinkage characteristics

The SWAP user needs to specify either the parameters of Kim's or Hendriks' relationship (see Section 6.1.1.2), or the values of typical points of the shrinkage characteristic curve. The different options and required parameters are listed in Table 6.1. The option to specify the original parameters of both relationships is especially relevant for the development of pedotransfer functions for shrinkage characteristics. Alterra is working on pedotransfer functions for shrinkage characteristics of clay and peat soils. The options to use typical points of the shrinkage characteristic curves are useful when limited information about the exact curves is available. When just a (rough) sketch of a curve is available it may be possible to recognize these typical points.

**Table 6.1** Overview of required shrinkage parameters for clay and peat soils (Figure 6.4.A and 6.9).

Soil	Input option	Shrinkage parameters				
		ShrParA	ShrParB	ShrParC	ShrParD	ShrParE
Clay	1	$\alpha_K (e_0)$	$\beta_K$	$\gamma_K$	–	–
	2	$\alpha_K (e_0)$	$\vartheta_a$	–	–	–
Peat	1	$e_0$	$\vartheta_a$	$\alpha_H$	$\beta_H$	$P_H$
	2	$e_0$	$\vartheta_a$	$\vartheta_r$	$\vartheta_p$	$P_H$
	3	$e_0$	$\vartheta_a$	$\vartheta_i$	$e_i$	–

For clay soils, the typical points are the void ratio  $e_0$  at  $\vartheta = 0$  ( $\alpha_K$ ) and the moisture ratio  $\vartheta_a$  at transition of normal to residual shrinkage (Figure 6.4.A). With these two input data, SWAP generates the parameters of Kim's relationship. For peat soils, there are two options to use typical points of the shrinkage curve. The first, option 2 in Table 6.1, requires typical points with which the parameters of Hendriks' curve can be generated. The second, option 3 in Table 6.1, enables to describe the shrinkage with three straight line-pieces.

**Figure 6.9** Construction of support-lines and line-pieces in the graph of the peat-shrinkage curve to find values of input parameters for Option 2 of Table 6.1: 'typical points' (left) and for Option 3 of Table 6.1: '3 straight line-pieces' (right). Symbols in circles represent input parameters.

Option 2 requires the construction of three support-lines,  $L_1$ ,  $L_2$  and  $L_3$ , in the graph of the shrinkage curve (Figure 6.9).  $L_1$  connects the points  $(0, e_0)$  and  $(\vartheta_s, e_s)$ .  $L_2$  is parallel to the saturation line and starts at point  $(0, e_0)$ .  $L_3$  connects the points  $(0, e_0^*)$  and  $(\vartheta_s, e_s^*)$  and is tangent to the shrinkage curve. In order to construct this line, parameter  $P_H$  should be found so that  $e_0^* = (1 + P_H) e_0$  and  $e_s^* = (1 + P_H) e_s$ . This can easily be done by trial-and-error in a spreadsheet or on paper. When  $P_H < 0$ ,  $L_2$  must start at point  $(0, \frac{1}{2}e_0)$  instead of point  $(0, e_0)$  (e.g. samples A-15 and V-10 in Appendix 11). For values of  $|P_H| < 0.1$ , option 3 is recommended (e.g. sample A-25 in Appendix 11). Input parameters are (Table 6.1):  $e_0$ ,  $P_H$ ,  $\vartheta_a$  (moisture ratio at transition of 'near-normal' to 'subnormal' shrinkage on  $L_1$ , Figure 6.4.B),  $\vartheta_r$  (moisture ratio at intersection point of  $L_2$  and curve) and  $\vartheta_p$  (moisture ratio at tangency point of  $L_3$  to curve). Values must be given with an accuracy of at least 1% of saturated moisture ratio ( $\vartheta_s$ ).

Option 3 requires the construction of three line-pieces  $L_{p1}$ ,  $L_{p2}$  and  $L_{p3}$  and one support-line  $L$  in the graph of the shrinkage curve (Figure 6.9).  $L_{p1}$  connects the points  $(0, e_0)$  and  $(\vartheta_i, e_i)$ ,  $L_{p2}$  the points  $(\vartheta_i, e_i)$  and  $(\vartheta_a, e_a)$ , and  $L_{p3}$  the points  $(\vartheta_a, e_a)$  and  $(\vartheta_s, e_s)$ .  $L$  connects the points  $(0, e_0)$  and  $(\vartheta_s, e_s)$ . Point  $(\vartheta_a, e_a)$  is situated on this line and represents the point of transition of 'near-normal' to 'subnormal' shrinkage. Point  $(\vartheta_i, e_i)$  should be chosen in such a way that the three line-pieces describe the shrinkage curve as accurate as possible. For use in the model,  $L_{p2}$  and  $L_{p3}$  are much more important than  $L_{p1}$ . So emphasis should be put on these two line-pieces. Input parameters are (Table 6.1):  $e_0$ ,  $\vartheta_a$ ,  $e_i$  and  $\vartheta_i$ .

```

If there is no information available to decide otherwise,  $\text{ThetCrMP}$  could be taken at 90-100%  $\theta_{\text{sat}}$ ,  $\text{GeomFac}$  as 3.0 and  $\text{ZnCrAr}$  around -5.0 cm.

Measured shrinkage characteristics of seven clay profiles in the Netherlands, as described by Bronswijk and Evers-Vermeer (1990), are listed in Appendix 10. Yule and Ritchie (1980a, 1980b) described shrinkage characteristics of eight Texas Vertisols, using small and large cores. Garnier et al. (1997) propose a simple evaporation experiment to determine simultaneously the moisture retention curve, hydraulic conductivity function and shrinkage characteristic. Measured shrinkage characteristics of four peat soil profiles in the Netherlands, as described by Hendriks (2004), are listed in Appendix 11.

### 6.3.2.2 Water flow

The input parameters of the water flow concept are listed in Box 6.2. They are discussed below.

The sorptivity parameters can be obtained by fitting Eq. (6.30) against measured values to derive a relationship between sorptivity and initial moisture content. The advantage of measured sorptivities is that they may reflect the influence of water-repellent coatings on the surface of clay aggregates which often hamper infiltration into these aggregates (Thoma et al., 1992; Dekker and Ritsema, 1996). If measured sorptivities are not available, sorptivity as a function of moisture content is derived from the soil hydraulic characteristics (Parlange, 1975). To account for water-repellent coatings a correction factor  $\text{SorpFacParl}$  can be entered. Greco et al. (1996) found values for this factor of 0.33 for the topsoil and 0.5 for the sub-soil of a Dutch clay soil similar to the Andelst soil. They describe a simple way of measuring sorptivity as a function of moisture content.

$\text{ShapeFacMp}$  can be used to decrease or increase exchange fluxes between macropores and soil matrix. Theoretically, its value lies between 1 and 2 (see Section 6.1.2); default value is 1.0.  $\text{RapDraResRef}$  depends on the system of macropores and their connection to drains or ditches. In case of a network of structural cracks,  $\text{RapDraResRef}$  will be smaller than in case of mainly hole shaped macropores. The opposite applies to  $\text{RapDraReaExp}$ .

---

# 7 Crop growth

## 7.1 Introduction

SWAP contains three crop growth routines: a simple module for a static crop and two detailed modules for dynamic crops: one for arable crops (WOFOST, WORld FOod STudies), and a detailed module for grass (re)growth. A static crop has a fixed development of leaf area index and rooting depth, independent of climatic conditions, whereas development of a dynamic crop changes with the climatic conditions.

The main function of the simple module for static crops is to provide proper upper boundary conditions for soil water movement. The simple model is useful when crop growth doesn't need to be simulated or when crop growth input data are insufficient. Section 7.2 provides a description of the simple module.

In the footsteps of De Wit and co-workers (De Wit et al., 1978; Goudriaan, 1977; Penning de Vries and Van Laar, 1982), in the 1980s a wide range of scientists in Wageningen became involved in the development and application of dynamic crop growth models. The generic crop model SUCROS for the potential production situation was developed (Spitters et al., 1989). SUCROS formed the basis of a range of Wageningen crop models, as reviewed by Bouman et al. (1996) and Van Ittersum et al. (2003). One of the developed models is the WOFOST model, which simulates in detail photosynthesis and crop development, taking into account growth reductions due to water and/or salt stress. WOFOST has been implemented in SWAP and is described in Section 7.3.

The detailed module for dynamic growth of grass is a modified version of WOFOST. The only species occurring in the sward is supposed to be perennial ryegrass (*Lolium perenne* L.). The sward is regular mowed or grazed and remains vegetative during the year. The settings for regrowth after grass cutting have a large effect on the leaf area development; therefore the application of this module requires expert judgement. The detailed module for growth of grassland is described in Section 7.4.

Section 7.5 describes the germination of crop growth, and Section 7.6 the option to simulate the impact of atmospheric CO<sub>2</sub> changes. Section 7.7 describes the option to activate soil and crop nitrogen modules which interact with WOFOST.

---

## 7.2 Simple module for static crop growth

The simple crop growth model represents a green canopy that intercepts precipitation, transpires water vapour and shades the ground. The user specifies crop variables as a function of development stage. The variables to be specified are crop height, rooting depth and either leaf area index or soil cover fraction. The development stage is controlled either by the temperature sum or can be linear in time.

The simple model does not calculate the crop potential or actual yield. However, users may define yield response factors (Doorenbos and Kassam, 1979; Smith, 1992) for various growing stages as a function of development stage. For each growing stage  $k$  the actual yield  $Y_{a,k}$  ( $\text{kg ha}^{-1}$ ) relative to the potential yield  $Y_{p,k}$  ( $\text{kg ha}^{-1}$ ) during this growing stage is calculated by:

$$1 - \frac{Y_{a,k}}{Y_{p,k}} = K_{y,k} \left( 1 - \frac{T_{a,k}}{T_{p,k}} \right) \quad (7.1)$$

where  $K_{y,k}$  (-) is the yield response factor of growing stage  $k$ , and  $T_{p,k}$  (cm) and  $T_{a,k}$  (cm) are the potential and actual transpiration, respectively, during growing stage  $k$ .

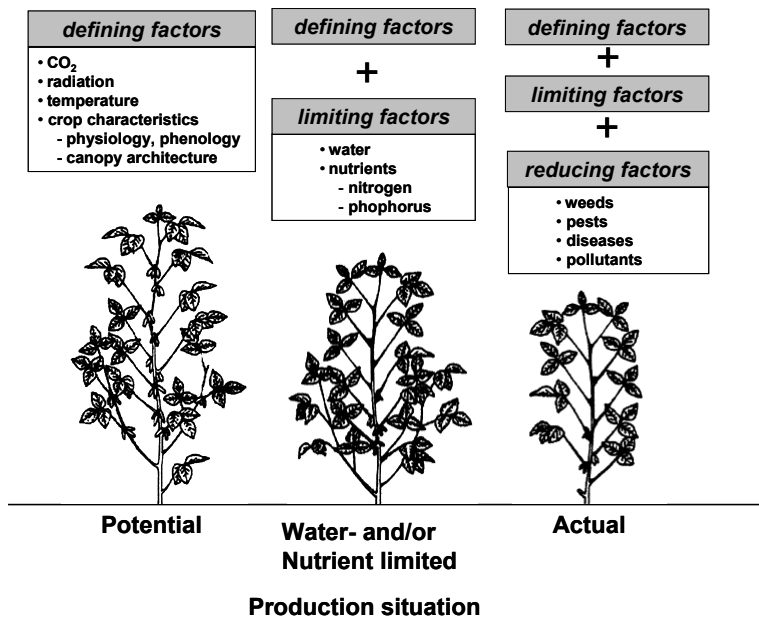

The relative yield of the whole growing season is calculated as the product of the relative yields of each growing stage:

$$\frac{Y_a}{Y_p} = \prod_{k=1}^n \left( \frac{Y_{a,k}}{Y_{p,k}} \right) \quad (7.2)$$

where  $Y_a$  is the cumulative actual yield ( $\text{kg ha}^{-1}$ ) of the whole growing season,  $Y_p$  is the cumulative potential yield ( $\text{kg ha}^{-1}$ ) of the whole growing season, index  $k$  is the growing stage and  $n$  is the number of defined growing stages.

## 7.3 Detailed module for dynamic growth of arable crops

Three groups of growth factors (Figure 7.1) can be distinguished to obtain a hierarchy of production levels in crop production (Van Ittersum et al., 2003). Growth defining factors, such as radiation intensity, carbon dioxide concentration, temperature and crop characteristics determine the potential production that can be achieved in a given physical environment and for a given plant species. To achieve the potential production the crop must be optimally supplied with water and nutrients and completely protected against weeds, pests, diseases and other factors that may reduce growth.

**Figure 7.1** A hierarchy of growth factors, production situations and associated production levels (Van Ittersum et al., 2003).

Growth-limiting factors such as water and nutrients determine the water- or nutrient-limited production level in a given physical environment. Through management of the water and nutrients availability, crop production may increase towards potential levels. Growth reducing factors that reduce or hamper growth comprise biotic factors such as weeds, pests and diseases, and abiotic factors such as pollutants. Crop protection aims at an effective management of these factors. In the actual production situation crop productivity is usually the results of a combination of growth-limiting and -reducing factors (Van Ittersum et al., 2003).

**Figure 7.2** Overview of crop growth processes incorporated in WOFOST.

WOFOST (Van Keulen and Wolf, 1986; Spitters et al., 1989; Supit et al., 1994; Hijmans et al., 1994; Boogaard et al., 1998) simulates potential and limited production due to water and/or salinity and/or nutrient stress. Figure 7.2 shows the processes and relations incorporated in WOFOST. The energy that is absorbed by the canopy depends on the incoming radiation, the crop leaf area and the photosynthetic leaf characteristics. With the absorbed radiation the potential gross photosynthesis is calculated, which is subsequently reduced due to water/salinity/nutrient stress yielding the actual gross photosynthesis.

Part of the produced carbohydrates ( $\text{CH}_2\text{O}$ ) are used for maintenance of the living biomass (maintenance respiration). The remaining carbohydrates are converted into structural matter. This conversion process costs energy and some weight is lost (growth respiration). The remaining dry matter is partitioned among roots, leaves, stems and storage organs, using partitioning factors that are a function of the phenological development stage (Spitters et al., 1989). The fraction partitioned to the leaves, determines leaf area development and hence the dynamics of light interception. Integrating the growth rates over time yields the dry weight of the crop organs. During the seasons, part of living biomass dies due to senescence.

Light interception and  $\text{CO}_2$  assimilation are the main growth driving processes. Some of these crop growth processes are influenced by temperature, like for example the maximum photosynthesis and the maintenance respiration rate. Other processes, like the assimilate partitioning and tissue decay, are a function of the phenological development stage (which is a function of the thermal time).

### 7.3.1 Phenological development stage

As many physiological and morphological processes change with the phenological stage, quantification of the phenological development is essential in any crop growth simulation model. For many annual crops, the phenological development can be expressed as a development stage  $D_s$  (-), having the value 0 at seedling emergence, 1 at flowering and 2 at maturity (Van Heemst, 1986a; 1986b). The most important phenological change is the one from vegetative ( $0 < D_s < 1$ ) to reproductive stage ( $1 < D_s < 2$ ), which changes drastically the dry matter allocation to organs.

Crop growth simulation starts either at sowing or emergence. The sowing or emergence date should be specified by the user. A crop passes through successive phenological development stages, of which the length depends on the development rate. Development rates before floral initiation or anthesis ( $D_s = 1$ ) are controlled by temperature and sometimes depend on day length as well. After anthesis the development rate only depends on the temperature. Higher temperatures accelerate the development rate, leading to shorter growing periods. It has often been demonstrated, that the development rate increases more or less linearly with temperature

**Figure 7.3** Example of effective temperature for temperature sum as function of daily average temperature.

(Van Dobben, 1962; Van Keulen and Seligman, 1987). Therefore WOFOST uses the temperature sum to describe the development stage. The temperature sum is calculated using the effective temperature  $T_{\text{eff}}$  (°C), which is a tabular function of the daily average temperature  $T_{\text{day}}$  (°C) (Figure 7.3). Generally for species originating from temperate regions  $T_{\text{day}} - T_{\text{eff}} = 0-3$  °C, while for species of subtropical and tropical origins  $T_{\text{day}} - T_{\text{eff}} = 9-14$  °C (Angus et al., 1981). Note that  $T_{\text{eff}}$  cannot be negative. The user should specify  $T_{\text{eff}}(T_{\text{day}})$  and the relation between crop development stage  $D_s$  and  $T_{\text{eff}}$ :

$$D_s^{j+1} = D_s^j + \frac{T_{\text{eff}}}{T_{\text{sum},i}} \quad (7.3)$$

where superscript  $j$  is the day number and  $T_{\text{sum},i}$  is the temperature sum required to complete either the vegetative or the reproductive stage. Within a species, cultivars may vary substantially in their temperature requirements.

For some species or cultivars the day length during the vegetative stage should be accounted for. Approaches that describe such effects quantitatively are given, amongst others, by Weir et al. (1984), Hadley et al. (1984) and Reinink et al. (1986). In Wofost a reduction factor for the development rate as function of day length  $f_{\text{day}}$  (-) is computed:

$$f_{\text{day}} = \frac{L_{\text{day}} - L_{\text{cday}}}{L_{\text{oday}} - L_{\text{cday}}} \quad \text{with} \quad 0 < f_{\text{day}} < 1 \quad (7.4)$$

with  $L_{\text{day}}$  the actual day length (d),  $L_{\text{cday}}$  the critical day length for development (d), and  $L_{\text{oday}}$  the optimum day length for development (d). The critical and the optimum day length should be provided by the user. Note that in modern cultivars, photosensitivity is much less pronounced than in traditional cultivars and the day length influence can be ignored by choosing an appropriate temperature sum, which leads to an equivalent crop life cycle.

Crop growth simulation stops when the development stage reaches ripeness ( $D_s = 2$ ) or when the crop will be harvested (i.e. before ripeness). In this later case the user should specify the harvest date.

### 7.3.2 Radiation fluxes above the canopy

Measured or estimated daily global radiation (wave length range 300 - 3000 nm) is input for the model. Incoming radiation is partly direct, with the angle of incidence equal to the angle of the sun, and partly diffuse, with incidence under various angles. The sine of solar elevation as a function of the day hour, can be calculated with:

$$\sin \beta_{\text{sun}} = \sin L_g \sin \sigma_{\text{sun}} + \cos L_g \cos \sigma_{\text{sun}} \cos \left( \frac{2\pi(t_h + 12)}{24} \right) \quad (7.5)$$

with  $\beta_{\text{sun}}$  is the solar elevation (degrees),  $\sigma_{\text{sun}}$  is solar declination (degrees),  $L_g$  is geographic latitude (degrees) and  $t_h$  is hour of the day. Integration of  $\sin \beta_{\text{sun}}$  over the day and multiplication with the solar constant yields the daily extra-terrestrial radiation which is also known as the Angot radiation ( $\text{J m}^{-2} \text{d}^{-1}$ ):

$$R_o = S_c \int \sin \beta_{\text{sun}} dt \quad (7.6)$$

The solar constant  $S_c$  ( $\text{J m}^{-2} \text{d}^{-1}$ ) can be calculated as:

$$S_c = 1370 \left( 1 + 0.033 \cos \left( \frac{2j\pi}{365} \right) \right) \quad (7.7)$$

where  $j$  is the day number in the year (DOY). Only about 50 percent of the global radiation is photosynthetically active (PAR, Photosynthetically Active Radiation, wavelength band 400-700 nm). The daily incoming PAR ( $\text{J m}^{-2} \text{d}^{-1}$ ) is calculated by multiplying half of the daily global radiation with the ratio of the actual effective solar elevation and the integral of the effective solar height, taking into account reduced atmospheric transmission at low solar elevations:

$$PAR = 0.5 R_g \frac{\sin \beta_{\text{sun}} (1 + 0.4 \sin \beta_{\text{sun}})}{\int \sin \beta_{\text{mod, sun}}} \quad (7.8)$$

where  $R_g$  is daily global radiation ( $\text{J m}^{-2} \text{d}^{-1}$ ) and  $\int \sin \beta_{\text{mod, sun}}$  the integral of  $\sin \beta_{\text{sun}}$  over the day (-) which is corrected for reduced atmospheric transmission at low solar elevations. See Spitters et al. (1986).

The diffuse radiation flux results from scattering of sun rays by clouds, gases and dust in the atmosphere. To quantify the diffuse radiation first the atmospheric transmission is calculated as:

$$T_{\text{atm}} = \frac{R_g}{R_o} \quad (7.9)$$

The relation between the proportion of the diffuse flux in the global irradiance ( $R_{df}/R_g$ ) and the atmospheric transmission  $T_{\text{atm}}$  is characterized by an approximately linear trend for transmissions ranging between 0.35 and 0.75. At low transmissions, nearly all of the incoming radiation is diffuse so that the curve bends off. There is some variation among published relations, arising from differences in atmospheric conditions, especially relative sunshine duration, water content of the atmosphere, and cloud type, but also lack of fit of the presented regression equation from the data and differences in the method of measuring the diffuse radiation. The relation used in WOFOST has been derived by de Jong (1980) and has been recommended by Spitters et al. (1986):

$$\frac{R_{df}}{R_g} = 1 \quad \text{for } T_{\text{atm}} \leq 0.07 \quad (7.10)$$

$$\frac{R_{df}}{R_g} = 1 - 2.3(T_{\text{atm}} - 0.07)^2 \quad \text{for } 0.07 < T_{\text{atm}} \leq 0.35$$

$$\frac{R_{df}}{R_g} = 1.33 - 1.46T_{\text{atm}} \quad \text{for } 0.35 < T_{\text{atm}} \leq 0.75$$

$$\frac{R_{df}}{R_g} = 0.23 \quad \text{for } T_{\text{atm}} > 0.75$$

The diffuse photosynthetically active radiation  $PAR_{dif}$  ( $J m^{-2} d^{-1}$ ) can be calculated by:

$$PAR_{dif} = 0.5 \frac{R_{df}}{R_g} T_{atm} R_o \quad (7.11)$$

The direct radiation flux,  $PAR_{dir}$  ( $J m^{-2} d^{-1}$ ), is obtained by subtracting the diffuse part from the photosynthetically active radiation flux:

$$PAR_{dir} = PAR - PAR_{dif} \quad (7.12)$$

### 7.3.3 Radiation profiles within the canopy

The incoming PAR is partly reflected by the canopy. The reflection coefficient is defined as the fraction of the downward radiation flux that is reflected by the entire canopy. The reflection coefficient  $\rho_{rad}$  (-) of a green leaf canopy with a random spherical leaf angle distribution equals (Goudriaan, 1977):

$$\rho_{rad} = \left( \frac{1 - \sqrt{1 - \sigma_{leaf}}}{1 + \sqrt{1 - \sigma_{leaf}}} \right) \left( \frac{2}{1 + 1.6 \sin \beta_{sun}} \right) \quad (7.13)$$

with  $\sigma_{leaf}$  the scattering coefficient of single leaves for visible radiation (-), which is set to 0.2 (Goudriaan, 1977). The first right-hand-side term of Eq. (7.13) denotes the reflection of horizontal leaves and the second term is the approximate correction factor for a spherical leaf angle distribution. The fraction  $(1 - \rho_{rad})$  of the incoming visible radiation is available for absorption by the canopy.

Light intensity, adjusted for crop reflection, decreases approximately exponentially with leaf area index when going deeper into the canopy:

$$PAR_L = (1 - \rho_{rad}) PAR e^{-\kappa L} \quad (7.14)$$

where  $L$  is the cumulative leaf area index,  $\Sigma LAI$  ( $m^2$  leaf  $m^{-2}$  ground), counted from the top of the canopy downwards,  $PAR_L$  is the net light intensity ( $J m^{-2} d^{-1}$ ) at depth  $L$ , and  $\kappa$  is the radiation extinction coefficient (-).

The profiles of the net diffuse flux and the net flux caused by direct irradiance can be characterized analogously (Goudriaan, 1982). Diffuse and direct fluxes each attenuate at a different rate, and both extinction coefficients are input in SWAP. For a random spherical leaf angle distribution the extinction coefficient of the direct flux component,  $\kappa_{dir}$  (-), might be approximated by (Goudriaan, 1977, 1982):

$$\kappa_{dir} = \frac{0.5}{\sin \beta_{sun}} \quad (7.15)$$

and the extinction coefficient of the diffuse flux component,  $\kappa_{dif}$  (-), might be calculated as:

$$\kappa_{dif} = \kappa_{dir} \sqrt{1 - \sigma_{leaf}} \quad (7.16)$$

In Eq. (7.15), the factor 0.5 represents the average projection on the ground surface of leaves showing a spherical angle distribution. Averaging  $0.5/\sin\beta$  during a day with an overcast sky, gives a value of  $\kappa_{dir} = 0.8$  (-). The value of  $\kappa_{dir}$  can be measured directly under completely overcast sky conditions, when only diffuse radiation reaches the canopy. The average value is about 0.72 (-) (Goudriaan, 1977).

In many situations, the leaf angle distribution is not spherical. Therefore, in WOFOST the actual leaf angle distribution is accounted for by using a so called cluster factor which is the measured extinction coefficient for diffuse radiation, relative to the theoretical one for a spherical leaf area distribution.

On its way through the canopy, part of the direct flux is intercepted and scattered by the leaves. Hence, the direct flux segregates into a diffuse, scattered component and another component which remains direct. Attenuation of the remaining direct component proceeds like in a hypothetical canopy of black, non scattering leaves. The diffuse component is obtained as the difference between the total direct flux and its direct component.

The light absorption rate at depth  $L$  in the canopy,  $PAR_{L,a}$  ( $J\ m^{-2}\ leaf\ d^{-1}$ ), is the derivative of Eq. (7.14) with respect to  $L$ :

$$PAR_{L,a} = \kappa(1 - \rho_{rad})PAR e^{-\kappa L} \quad (7.17)$$

Similar expressions can be derived for the separate light components: the diffuse flux, the total direct radiation flux and the direct component of the direct radiation flux. The absorbed diffuse component of the direct flux is obtained by subtracting the direct component from the total direct flux.

### 7.3.4 Instantaneous assimilation rates per leaf layer

The canopy  $CO_2$  assimilation rate layer is obtained by substituting the absorbed amount of light energy into the assimilation-light response of single leaves (Peat, 1970):

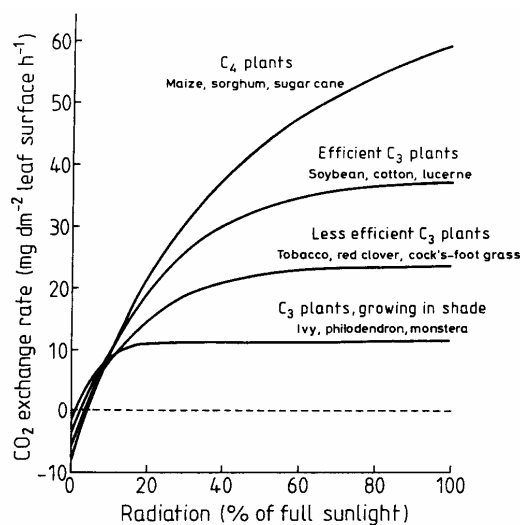

$$A_L = A_{max} \left( 1 - e^{-\frac{\epsilon_{PAR} PAR_{L,a}}{A_{max}}} \right) \quad (7.18)$$

where  $A_L$  is the gross assimilation rate at relative depth  $L$  ( $kg\ CO_2\ m^{-2}\ leaf\ d^{-1}$ ),  $A_{max}$  the gross assimilation rate at light saturation ( $kg\ CO_2\ m^{-2}\ leaf\ d^{-1}$ ), and  $\epsilon_{PAR}$  the initial slope or light use efficiency ( $kg\ CO_2\ J^{-1}$  absorbed).

Two leaf classes are distinguished: shaded leaves and sunlit leaves. The shaded leaf area absorbs the diffuse flux and the diffuse component of the direct flux. The sunlit leaf area receives diffuse and direct radiation. At every horizon within the canopy, the intensity of the unobstructed direct beam equals its intensity above the crop. Illumination intensity of sunlit leaves varies strongly with leaf angle. In the model, the assimilation rate of the sunlit leaf area is therefore integrated over the leaf angle distribution.

The assimilation rate per unit leaf area in a canopy, is the sum of the assimilation rates of sunlit and shaded leaves, taking into account their proportion in each layer. The proportion of sunlit leaf area at depth  $L$  in the canopy equals the proportion of the direct component of the direct flux reaching that depth. This proportion is calculated analogous to Eq. (7.17), using the extinction coefficient of the direct radiation component.

Figure 7.4 shows the  $CO_2$  assimilation rate at different sunlight intensities as measured for various crops. Striking are the higher assimilation rates of so-called  $C_4$  crops in comparison to  $C_3$  crops. The reason is that  $C_4$  plants are more effective in  $CO_2$  fixation within a leaf (Moene and Van Dam, 2014).

**Figure 7.4**  $CO_2$  exchange rate as function of radiation amount for  $C_3$  and  $C_4$  plants.

At a certain light intensity, the  $CO_2$  uptake rate and the photosynthesis are much higher in case of  $C_4$  plants.

### 7.3.5 Daily gross assimilation rate of the canopy

The maximum instantaneous CO<sub>2</sub> assimilation rate  $A_{\max}$  (kg CO<sub>2</sub> ha<sup>-1</sup> d<sup>-1</sup>) is crop and development stage dependent and should be provided by the user as function of development stage.  $A_{\max}$  has to be corrected for the atmospheric CO<sub>2</sub> concentration and for the average daytime temperature  $T_{\text{day}}$  (°C) and according to:

$$A_{\text{pgross}}^1 = f_{\text{CO}_2} f_{\text{tday}} A_{\max} \quad (7.19)$$

where  $f_{\text{CO}_2}$  is the [CO<sub>2</sub>] dependent correction factor and  $f_{\text{tday}}$  is the average daytime temperature that corrects  $A_{\max}$  for sub-optimum temperatures. Both correction factors are crop specific and should be provided by the user as tables. The average daytime temperature  $T_{\text{day}}$  (°C) is calculated as:

$$T_{\text{day}} = 0.75 T_{\max} + 0.25 T_{\min} \quad (7.20)$$

Figure 7.5 shows a typical occurrence of the daytime dependent correction factor.

**Figure 7.5** Reduction factor for the influence of day time average temperature on A<sub>MAX</sub>.

In a next step, the instantaneous rates per leaf layer are integrated over the canopy leaf area index and over the day using the Gaussian integration method (Press et al., 1989). This method specifies the discrete points at which function values have to be calculated, and the weighting factors with which the function values have to be multiplied in order to minimize deviation from analytical integration. A three-point algorithm evaluates the function at  $0.1127a$ ,  $0.5a$  and  $0.8873a$  of the interval  $(0, a)$ , with weighting coefficients 1.0, 1.6 and 1.0, respectively. The Gaussian integration method is remarkably accurate in case of trigonometric (radiation) and exponential (light absorption) functions. WOFOST computes at three selected moments of the day incoming PAR just above the canopy. Using this radiation, assimilation is computed at three selected depths in the canopy (Spitters et al., 1989). Gaussian integration of these values results in the daily gross CO<sub>2</sub> assimilation rate,  $A_{\text{pgross}}$  (kg CO<sub>2</sub> ha<sup>-1</sup> d<sup>-1</sup>).

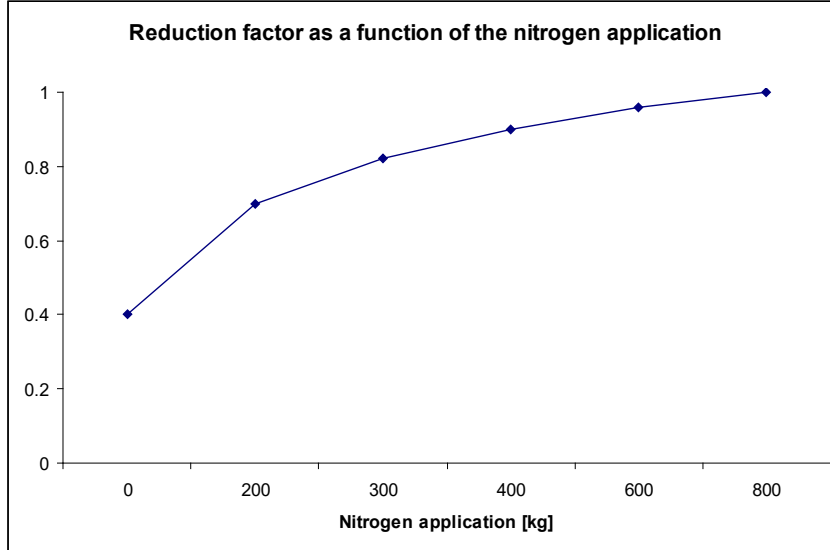

For each kg of absorbed CO<sub>2</sub> 30/44 kg biomass (CH<sub>2</sub>O) is formed. Factors that reduce the daily assimilation rate are unfavourable temperatures, water shortage or excess, salinity and nutrient stress:

$$A_{\text{gross}} = \frac{30}{44} f_{7\min} \left( \min\left(\frac{T_a}{T_p}, f_{\text{nstress}}\right) \right) A_{\text{pgross}}^1 \quad (7.21)$$

where  $A_{\text{gross}}$  is the daily gross assimilation rate (kg ha<sup>-1</sup> d<sup>-1</sup>),  $T_a$  is de actual transpiration reduced by, water, oxygen, salinity and frost stress, see equation (3.18 and 3.19),  $f_{\text{nstress}}$  is the nutrient stress and  $f_{7\min}$  is stress caused by low temperatures. At night, assimilates produced during daytime, are transformed into structural biomass. This process is hampered by low temperature. If these low temperatures prevail for several days, the assimilation rate diminishes and ultimately halts. In WOFOST  $f_{7\min}$  is a function of the minimum temperature during the previous seven days.  $T_p$  is the potential transpiration and  $T_a$  is de actual transpiration reduced by, water, oxygen, salinity and frost stress, see

Section 3.5. Factor  $f_{\text{nstress}}$  accounts for nutrient stress that is calculated as function of the crop nutrient status and supply by either artificial fertilizer, slurry or compost. The crop nutrient status is based on Shibu et al. (2010). Soil nitrogen fate is described by Groenendijk et al. (2016).

The nitrogen stress factor depends on the nitrogen application and the crop nitrogen uptake. Not all applied fertilizer will be consumed by the crop. In SWAP the reduction factor is input as function of the applied Nitrogen amount (kg) (Figure 7.6).

**Figure 7.6** Reduction factor for influence of nitrogen supply on on AMAX (Source: Nitrogen fluxes in intensive grassland systems. Van der Meer et al. (1986).

### 7.3.6 Maintenance respiration

Some of the carbohydrates formed are respired to provide energy for maintaining the existing bio structures. This maintenance respiration consumes roughly 15 - 30% of the carbohydrates produced by a crop in a growing season (Penning de Vries et al., 1979). This underlines the importance of accurate quantification of this process in the model.

WOFOST estimates the maintenance costs using the approach proposed by Penning de Vries and Van Laar (1982), assuming that the reference maintenance requirements  $R_{\text{mref}}$  ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) are proportional to the dry weights of the plant organs to be maintained:

$$R_{\text{mref}} = c_{\text{m,leaf}} W_{\text{leaf}} + c_{\text{m,stem}} W_{\text{stem}} + c_{\text{m,stor}} W_{\text{stor}} + c_{\text{m,root}} W_{\text{root}} \quad (7.22)$$

where  $c_{\text{m},i}$  denotes the maintenance coefficient of organ  $i$  ( $\text{kg kg}^{-1} \text{d}^{-1}$ ) and  $W_i$  the organ dry weight ( $\text{kg ha}^{-1}$ ). The maintenance coefficients should be specified by the user.

The maintenance respiration rate still has to be corrected for senescence and temperature. The reduction factor for senescence  $f_{\text{senes}}$  (-) is crop-specific and is defined as a function of development stage. Higher temperatures accelerate the turnover rates in plant tissue and hence the costs of maintenance. An increase in temperature of  $10^\circ\text{C}$  increases maintenance respiration by a factor of about 2 (Kase and Catsky, 1984; Penning de Vries and Van Laar, 1982). However, to be more flexible, the user may specify the increase factor of the respiration rate per  $10^\circ\text{C}$  temperature increase,  $Q_{10}$  (-):

$$R_{\text{m}} = f_{\text{senes}} R_{\text{mref}} Q_{10}^{\frac{T_{\text{avg}} - 25}{10}} \quad (7.23)$$

where  $R_{\text{m}}$  is the actual maintenance respiration rate ( $\text{kg ha}^{-1} \text{d}^{-1}$ ).

It may be assumed that the vegetation will not be 'self-consuming' in terms of carbohydrates. Therefore the maintenance respiration rate cannot exceed the gross assimilation rate. The net assimilation rate  $A_{\text{net}}$  ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) is the amount of carbohydrates available for conversion into structural material:

$$A_{\text{net}} = A_{\text{gross}} - R_{\text{m}} \quad \text{with} \quad A_{\text{net}} \geq 0 \quad (7.24)$$

### 7.3.7 Dry matter partitioning and growth respiration

The primary assimilates in excess of the maintenance costs, are available for conversion into structural plant material. In this conversion process  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are released. The magnitude of growth respiration is determined by the composition of the end product formed (Penning de Vries et al., 1974). Thus the weight efficiency of conversion of primary photosynthates into structural plant material varies with the composition of that material. Fats and lignin are produced at high costs; structural carbohydrates and organic acids are relatively cheap. Proteins and nucleic acids form an intermediate group.

**Figure 7.7** Typical partitioning of assimilated dry matter among leaves, stem, roots and storage organs as function of development stage.

At higher temperatures the conversion processes are accelerated, but the pathways are identical (Spitters et al. 1989). Hence, the assimilate requirements do not vary with temperature.

In the vegetative stage, the increase in total dry weight of the crop is partitioned over the plant organs: roots, leaves, stems and storage organs. Storage organs, however, may not only be formed from current photosyntheses but also from carbohydrates and proteins that have been stored temporarily in vegetative parts and that are redistributed during the reproductive stage. In WOFOST this redistribution process is not incorporated.

The partitioning factor depends on the crop development stage. Figure 7.7 gives a typical example. The partitioning factors are input to the model. WOFOST first divides the gross dry matter among roots and shoots (leaves, stems and storage organs together), using the partitioning factor for roots,  $\xi_{\text{root}}$  (-). Next WOFOST divides the gross dry matter directed to the shoots among leaves, stems and storage organs, using the partitioning factors for these plant organs. At any development stage the sum  $\xi_{\text{leaf}} + \xi_{\text{stem}} + \xi_{\text{stor}}$  must equal one.

For losses during conversion of general carbohydrates to specific plant tissues, average (crop specific) conversion factors  $C_{e,i}$  ( $\text{kg kg}^{-1}$ ) should be specified for leaf, storage organ, stem and root biomass. WOFOST calculates a weighted average,  $C_e$  ( $\text{kg kg}^{-1}$ ), of these organ specific conversion factors by multiplying the organ specific values with the partitioning factors:

$$C_e = \frac{1}{\left( \frac{\xi_{\text{leaf}}}{C_{e,\text{leaf}}} + \frac{\xi_{\text{stor}}}{C_{e,\text{stor}}} + \frac{\xi_{\text{stem}}}{C_{e,\text{stem}}} \right) (1 - \xi_{\text{root}}) + \frac{\xi_{\text{root}}}{C_{e,\text{root}}}} \quad (7.25)$$

where  $\xi_j$  is the partitioning factor for organ  $i$ .

The gross dry matter growth rate  $w_{\text{gross}}$  ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) is related to the net assimilation rate  $A_{\text{net}}$  by:

$$w_{\text{gross}} = C_e A_{\text{net}} \quad (7.26)$$

Gross dry matter growth is first partitioned between shoots (leaves, stems and storage organs together) and roots:

$$w_{\text{gross,root}} = \xi_{\text{root}} w_{\text{gross}} \quad \text{and} \quad w_{\text{gross,sh}} = (1 - \xi_{\text{root}}) w_{\text{gross}} \quad (7.27)$$

where  $\xi_{\text{root}}$  is the partitioning factor for roots (-) and  $w_{\text{gross,root}}$  and  $w_{\text{gross,sh}}$  are the gross growing rates ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) of the roots and the shoots, respectively. The gross growth rate of leaves, stems and storage organs is simply the product of the gross dry matter growth rate of the shoots and the fraction allocated to these organs.

### 7.3.8 Carbon balance check

The actual gross  $\text{CO}_2$  assimilation rate has to be identical to the amount of structural plant material produced plus the amounts used for maintenance respiration and conversion. The carbon balance has to be zero and is implemented as:

$$0 = \frac{R_d - R_{m,T} - R_g * (\xi_{\text{root}} + (\xi_{\text{leaf}} + \xi_{\text{stem}} + \xi_{\text{stor}}) * (1 - \xi_{\text{root}})) * (D_{mi} / C_e)}{R_d} \quad (7.28)$$

where  $R_g$  is the growth respiration rate ( $\text{kg ha}^{-1} \text{d}^{-1}$ ),  $R_d$  is the actual daily  $\text{CH}_2\text{O}$  assimilation rate ( $\text{kg ha}^{-1} \text{d}^{-1}$ )  $R_{m,T}$  is the maintenance respiration rate ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) and  $\xi_j$  are partitioning factors (-) of organ  $i$  (i.e. leaves, stems and roots).  $D_{mi}$  is the dry matter increase.

WOFOST assumes that maintenance respiration cannot exceed the actual gross assimilation rate. However, in case the daily  $\text{CH}_2\text{O}$  assimilation rate comes close to zero, the maintenance respiration rate and the growth respiration rate also becomes small and a situation may occur that the numerator of the above mentioned equation becomes very small and negative. Introducing a division by  $R_d$  in the carbon check will identify such an event.

### 7.3.9 Senescence

The death rate of storage organs is assumed to be zero. The death rate of stem and roots is crop specific and is defined as the daily amount of the living biomass that no longer participates in the plant processes. The death rate of stems and roots is considered to be a function of development stage as specified by the user.

The death rate of leaves is more complicated. Leaf senescence occurs due to water stress, shading (high LAI), and also due to exceedance of the life span.

The potential death rate of leaves due to water stress  $\zeta_{\text{leaf,water}}$  ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) is calculated as:

$$\zeta_{\text{leaf,water}} = W_{\text{leaf}} \left( 1 - \frac{T_a}{T_p} \right) \zeta_{\text{leaf,p}} \quad (7.29)$$

where  $W_{\text{leaf}}$  is the leaf dry matter weight ( $\text{kg ha}^{-1}$ ),  $T_a$  and  $T_p$  are the actual and potential transpiration rates ( $\text{cm d}^{-1}$ ), respectively, and  $\zeta_{\text{leaf,p}}$  is the maximum relative death rate of leaves due to water stress ( $\text{kg kg}^{-1} \text{d}^{-1}$ ). The latter is crop specific and should be provided by the user.

A potential death rate due to self-shading,  $\zeta_{\text{leaf,shade}}$  ( $\text{kg ha}^{-1} \text{d}^{-1}$ ), is defined which increases linearly from zero at a critical leaf area index  $LAI_c$  (-), to its maximum value at  $2LAI_c$ :

$$\zeta_{\text{leaf,shade}} = 0.03 W_{\text{leaf}} \left( \frac{LAI - LAI_c}{LAI_c} \right) \quad \text{with} \quad 0 < \left( \frac{LAI - LAI_c}{LAI_c} \right) < 1 \quad (7.30)$$

with  $LAI_c = 3.2/\kappa_{\text{df}}$ . Typical values for  $\zeta_{\text{leaf,p}}$  and  $LAI_c$  are  $0.03 \text{ d}^{-1}$  and  $4 \text{ m}^2 \text{m}^{-2}$ , respectively (Spitters et al., 1989).

WOFOST uses the highest value of  $\zeta_{\text{leaf,water}}$  and  $\zeta_{\text{leaf,shade}}$  for the combined effect of water stress and mutual shading.

Leaves that have escaped from premature death due to water stress or mutual shading, inevitably die due to exceedance of the life span for leaves. Life span is defined as the maximum time a leaf can live at a constant temperature of  $35^\circ\text{C}$ . A physiologic ageing factor,  $f_{\text{age}}$  (-), is calculated each day:

$$f_{\text{age}} = \frac{T - T_{\text{b,age}}}{35 - T_{\text{b,age}}} \quad \text{with} \quad f_{\text{age}} \geq 0 \quad (7.31)$$

with  $T_{\text{b,age}}$  the lower threshold temperature for physiologic ageing ( $^\circ\text{C}$ ), which is crop specific and should be provided by the user.

The integral of the physiologic ageing factor over time yields the physiologic age,  $P_{\text{age}}$  (d):

$$P_{\text{age}}^{j+1} = P_{\text{age}}^j + f_{\text{age}} \Delta t \quad (7.32)$$

To correct for leaf senescence, the specific leaf area of each day,  $S_{\text{la}}^j$  ( $\text{ha kg}^{-1}$ ), the growth of the dry matter weight of leaves per day,  $w_{\text{leaf}}$ , and the physiological age,  $P_{\text{age}}$ , are stored in 3 corresponding arrays. The first element of the arrays represents the most recent day and the last element of the arrays represents the oldest day.

The leave weight that died during a day due to water stress or mutual shading is subtracted from the weight of the oldest leaf class. When senescence is larger than the amount available in the oldest leaf class, the remaining senescence is subtracted from the next oldest leaf class. Emptying of the leaf classes continues, until the amount of senescence is dissipated completely or the remaining amount of leaves becomes zero.

Leaves may maximally attain the age defined by the crop specific life span. WOFOST checks the leaf classes ages. The first class younger than the defined life span becomes the oldest class.

The stem death rate due to water stress is calculated in a similar way as the leaf death rate due to water stress using the same factor for the maximum relative death rate:

$$\zeta_{\text{stem,water}} = W_{\text{stem}} \left( 1 - \frac{T_a}{T_p} \right) \zeta_{\text{stem,p}} \quad (7.33)$$

where  $\zeta_{\text{stem,water}}$  is the stem death rate due to water stress ( $\text{kg ha}^{-1} \text{d}^{-1}$ ),  $\zeta_{\text{stem,p}}$  is the maximum relative leaf death rate due to water stress ( $\text{kg ha}^{-1} \text{d}^{-1}$ ),  $W_{\text{stem}}$  is the stem dry matter weight ( $\text{kg ha}^{-1}$ ) and  $T_a$  and  $T_p$  are the actual and potential transpiration respectively ( $\text{cm d}^{-1}$ ).

### 7.3.10 Net growth

The initial amount of total dry crop weight should be provided by the user. This amount is multiplied by the partitioning factors,  $\xi_i$ , to yield the dry weight values at emergence.

The net growth rates of the plant organs,  $w_{\text{net},i}$  ( $\text{kg ha}^{-1} \text{d}^{-1}$ ) result from the gross growth rates (Section 7.8) and the senescence rates,  $\zeta_i$  ( $\text{kg kg}^{-1} \text{d}^{-1}$ ):

$$w_{\text{net},i} = w_{\text{gross},i} - \zeta_i W_i \quad (7.34)$$

By integrating  $w_{\text{net},i}$  over time, the dry matter weight of organ  $i$ ,  $W_i$  ( $\text{kg ha}^{-1}$ ), is calculated.

An exception has to be made for the growth of leaves. In the initial stage, the rate of leaf appearance and final leaf size are constrained by temperature through its effect on cell division and extension, rather than by the supply of assimilates. For a relative wide range of temperatures the growth rate responds more or less linearly to temperature (Hunt et al., 1985; Causton and Venus, 1981; Van Dobben, 1962). The growth rate of the leaf area index,  $w_{\text{LAI}}$  ( $\text{ha ha}^{-1} \text{d}^{-1}$ ), in this so-called exponential stage, is described by:

$$w_{\text{LAI}} = \text{LAI} w_{\text{LAI,max}} T_{\text{eff}} \quad (7.35)$$

where  $w_{\text{LAI,max}}$  is the maximum relative increase of leaf area index ( $^{\circ}\text{C}^{-1} \text{d}^{-1}$ ).

WOFOST assumes that the exponential growth rate of leaf area index will continue until it equals the assimilation limited growth rate of the leaf area index. During this second, source limited growth stage,  $w_{\text{LAI}}$  is described by:

$$w_{\text{LAI}} = w_{\text{net,leaf}} S_{\text{la}} \quad (7.36)$$

where  $S_{\text{la}}$  is the specific leaf area ( $\text{ha kg}^{-1}$ ).

The green parts of stems and storage organs, may absorb a substantial amount of radiation. Therefore the so-called green area index  $\text{GAI}_i$  ( $\text{ha ha}^{-1}$ ) should be added to the leaf area index. The green area index of the stems and storage organs, are calculated from the dry matter weights of the organs:

$$\text{GAI}_i = S_{\text{ga},i} W_i \quad (7.37)$$

with  $S_{\text{ga},i}$  the specific green area ( $\text{ha kg}^{-1}$ ) of either stems or storage organ.  $S_{\text{ga},i}$  are crop specific and should be provided by the user.

### 7.3.11 Root growth

Root extension is computed in a straightforward way. The user needs to specify the initial rooting depth, the maximum rooting depth as determined by the crop and by the soil, and the maximum daily increase in rooting depth,  $d_{\text{root,max}}$  (cm). SWAP offers 2 methods to calculate actual rooting depth:

1. Daily increase in rooting depth is equal to the maximum daily increase, unless maximum rooting depth is reached or no assimilates are available for root growth:

$$D_{\text{root}}^j = D_{\text{root}}^{j-1} + d_{\text{root,max}} \quad \text{with} \quad D_{\text{root}}^j \leq D_{\text{root,max}} \quad \text{and} \quad w_{\text{net,root}} \geq 0 \quad (7.38)$$

where  $D_{\text{root}}^j$  is the rooting depth (cm) at day  $j$ .

2. Daily increase in rooting depth depends on relative dry matter increase:

$$D_{\text{root}}^j = D_{\text{root}}^{j-1} + \frac{\text{DMI}^j}{\text{DMI}_{\text{pot}}^j} d_{\text{root,max}} \quad \text{with} \quad D_{\text{root}}^j \leq D_{\text{root,max}} \quad (7.39)$$

where  $\text{DMI}^j$  is the dry matter increase of the actual crop at day  $j$  and  $\text{DMI}_{\text{pot}}^j$  is the dry matter increase of the potential crop.

## 7.4 Detailed module for dynamic growth of grass

The detailed module for dynamic growth of grass is a modified version of WOFOST. Unlike common agricultural crops, grass is perennial and stays in the vegetative stage during most of its growing season. Therefore the grass growth module deviates from the standard WOFOST. For instance the forcing functions are a function of Julian day number instead of crop development stage. Another example is grass rooting depth, which is directly related to simulated root dry matter.

Also cultivation of grass is quite different from common crops. Grass can be regularly mowed or consumed by cattle. In SWAP mowing is triggered by either a minimum amount of above ground dry matter or by a fixed date. The dry matter threshold can be defined as a constant or may vary during the season (Figure 7.8). Alternatively, the timing of a mowing event can be overruled by a maximum duration of grass growth. Note that mowing should occur within 6 weeks after the previous event in order to conserve the nutritional value of the grass. The total weight above ground biomass remaining on the field after mowing is specified by the user.

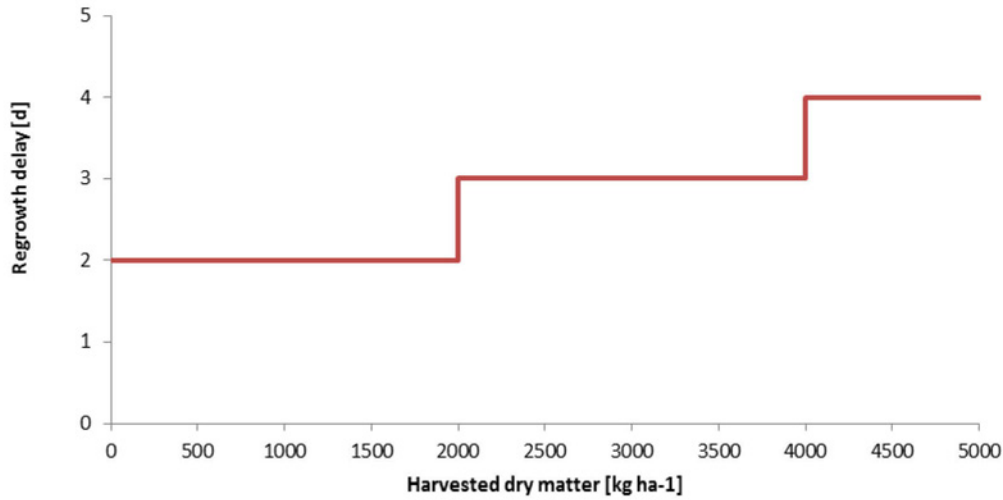

In a similar way cattle is allowed to enter the field after a specified minimum amount of above ground dry matter is exceeded. This threshold remains constant during the season. Cattle grazing can also be initiated at specific dates. In latter case still the minimum threshold of above ground dry matter should be reached before grazing starts. Grazing differs from mowing in this respect that the consumed biomass depends on the grazing days and the livestock density. In a table the user should specify the relation between livestock density, biomass consumption as well as dry matter losses due to manure droppings and treading.

After harvest, the leave and stem weights are reset according to the partitioning factors. The leaf area index is reset based on the leave weight. Experiments show that mowing does impede growth for a number of days. This regrowth delay is a function of the dry matter harvest and is part of the input. An example is given in Figure 7.9.

Note that the grass module is experimental. The supplied input values are calibrated for Dutch conditions and may not be appropriate for other climatic zones.

**Figure 7.8** Example of mowing regime.

**Figure 7.9** Example of regrowth delay after mowing.

## 7.5 Initialisation of crop growth (Germination)

### 7.5.1 Arable crops

For germination the method of Van Wijk et al. (1988) was implemented similar to Van Walsum and Van der Bolt (2013). Germination depends on temperature:

- $T_{av} < T_{min_{germ}}$  :  $Tsum_{germ} = Tsum_{germ}$
- $T_{min_{germ}} > T_{av} < T_{max_{germ}}$  :  $Tsum_{germ} = Tsum_{germ} + \frac{Tsum_{eme,opt}}{Tsum_{eme,sub}} * (T_{av} - T_{min_{germ}})$
- $T_{av} > T_{max_{germ}}$  :  $Tsum_{germ} = Tsum_{germ} + \frac{Tsum_{eme,opt}}{Tsum_{eme,sub}} * (T_{max_{germ}} - T_{min_{germ}})$

where  $T_{av}$  is the mean daily air temperature ( $^{\circ}C$ ) ( $= 0.5*(T_{min}+T_{max})$ ),  $T_{min_{germ}}$  is the minimum temperature for Tsum calculation ( $^{\circ}C*d$ ),  $T_{max_{germ}}$  is the maximum temperature for Tsum calculation ( $^{\circ}C*d$ ),  $Tsum_{germ}$  is the Tsum during the germination period ( $^{\circ}C*d$ ),  $Tsum_{eme,opt}$  is the Tsum for crop emergence under optimal soil moisture and temperature conditions ( $^{\circ}C*d$ ), and  $Tsum_{eme,sub}$  is the Tsum for crop emergence under sub-optimal soil moisture and temperature conditions ( $^{\circ}C*d$ ).

Tsum for crop emergence under sub-optimal soil moisture and temperature conditions is calculated for:

- too dry conditions as:  
 $TSUM_{eme,sub} = a * \log_{10}(-h_{rz}) + c$
- too wet conditions as:  
 $TSUM_{eme,sub} = -a * \log_{10}(-h_{rz}) + b$
- optimal conditions as:  
 $TSUM_{eme,sub} = TSUM_{eme,opt}$

where  $a$ ,  $b$ , and  $c$  are input parameters, and  $h_{rz}$  is the average pressure head of the upper 10 cm of the soil.

Emergence occurs when:  $Tsum_{germ} > Tsum_{eme,opt}$  .

---

## 7.5.2 Grasland

The initialisation of grass growth has 2 options with different thresholds to start growth:

- sum air temperatures or
- Soil temperature at particular depth

ad a) Select sum air temperatures > 200 °C. This requires a switch which will add positive daily air temperatures until sum > 200 °C.

ad b) Select soil temperature at particular depth. This requires a temperature threshold at a given depth and a time interval (days) during which the threshold should be exceeded.

## 7.6 CO<sub>2</sub> changes

The effect of increasing atmospheric CO<sub>2</sub> concentrations can be simulated using input of CO<sub>2</sub> concentrations and tables defining the relation between CO<sub>2</sub> concentration and maximum assimilation rate  $A_{max}$ , light use efficiency  $\epsilon_{PAR}$  and potential transpiration rate  $T_p$ , respectively. These relations vary per crop and also allow distinction between C<sub>3</sub> and C<sub>4</sub> crops.

This option is activated when 2 conditions are met: i) switch FLCO2 in the crop input file is present and set to true: FLCO2 = .TRUE. and ii) a file named "Atmosferic.co2" is present in the same directory/folder as the crop input file. An example and more detailed explanation are given by Groenendijk et al. (2016).

## 7.7 Nitrogen limited crop growth of arable crops

The core of the Soil-N module is a description of the nitrogen cycle, which is coupled to the organic matter cycle based upon the RothC-26.3 model.

This option also simulates nitrogen uptake and distribution in arable crops. The nitrogen routines, implemented in SWAP-WOFOST are based on Shibu et al. (2010). The carbon and nitrogen extensions for arable crops are described in more detail in a separate report (Groenendijk et al., 2016).

This option is activated with a switch (FLCROPNUT) in the .swp-file. An example and more detailed explanation are given by Groenendijk et al. (2016).

## 7.8 User instructions

### 7.8.1 Crop rotation scheme

* End of table
```

---

Box 7.1 shows an example of the input for the crop rotation scheme. Switch SWCROP determines whether a bare soil is simulated or a cultivated soil. For each crop the user should specify the type of initialisation, the cropping period, the crop name, the file name with crop input data and the type of growth module that should be used.

The output of crop results are written to an output file with the file name of the project (defined in \*.swp-file as PROJECT=) and an extension ".crp". Since crop rotation schemes with different combinations of CROPTYPE are allowed (see Box 7.1) we standardized the header of the output file and give an explanation in Appendix 18.

## 7.8.2 Simple crop module

An example of the input file is given in Box 7.2. Most data are specified as function of crop development stage, which ranges from 0 to 2. In part 1, the development stage can be defined either linear in time (specify only duration of crop growth) or based on the temperature sums in the vegetative and reproductive stage.

In part 2, light extinction coefficients are used to quantify the decrease of solar radiation within a canopy (Chapter 3). Default values of  $\kappa_{dir} = 0.8$  and  $\kappa_{dif} = 0.72$  will suffice in most cases.

In part 3, either leaf area or soil cover during crop development should be specified, in order to distribute evapotranspiration fluxes over evaporation and transpiration, as discussed in Chapter 3.

In part 4 a choice should be made between input of crop factors or crop heights. Crop factors should be used when  $ET_{ref}$  values are used as input, or when the Penman-Monteith method is used to calculate  $ET_{ref}$ . Crop heights should be specified if the potential evapotranspiration fluxes are derived directly for the actual crop (see Table 3.2). In that case also the reflection coefficient and stomatal resistance of the crop should be defined.

Rooting depth during crop development (part 5) in combination with a dimensionless root length density distribution (part 10) will be used by SWAP to determine the distribution of rootwater extraction rates.

In part 6, yield response factors as function of development stage should be specified. In case of a linear relation between  $Y_a/Y_p$  and  $T_a/T_p$  during the whole growing period, or when no information is available of the yield response factors as function of development stage  $D_s$  for the particular crop, specify  $K_{y,k} = 1$  for  $0 < D_s < 2$  and specify one growing stage  $k$ . Please, note that increasing the number of growing stages reduces the relative yield as calculated by Eq. (7.1).

Part 7 describes the reduction function of root water uptake for oxygen and drought stress. For oxygen stress options are available for the simple reduction function according to Feddes et al. (1978), or the more process based reduction of Bartholomeus et al. (2008). For drought stress the user should choose between the simple reduction function of Feddes et al. (1978), or the more process based reduction function of De Jong van Lier et al. (2008). Appendix 8 contains critical pressure head values of drought stress for Feddes et al. (1978) based on Taylor and Ashcroft (1972). The user may extend the original Feddes reduction function with compensation according to Jarvis (1989) by specifying a value for ALPHACRIT. This parameter denotes the value of relative transpiration until which reduction of root water uptake is compensated.

Part 8 specifies the parameters which describe the reduction of root water uptake as function of salinity concentrations. Options are available for the Maas and Hoffman reduction function, and reductions based on the osmotic head. Parameters for the Maas and Hoffman reduction function are available for many crops (Maas, 1990). Appendix 9 gives input parameters SALTMAX and SALTSLOPE for a number of crops.

Interception input data are specified in Part 9. For agricultural crops, just one interception coefficient (COFAB) for the Von Hoyningen-Hune and Braden concept is required. The default value of COFAB = 0.25 cm will suffice for most agricultural crops. In case of forests (Gash concept) SWAP requires

coefficients for free throughfall and stem flow, canopy storage capacity and average rainfall and evaporation fluxes as function of crop development. The specified average rainfall and evaporation fluxes values are independent of other input weather data.

Part 10 requires input of root density ( $\text{cm}/\text{cm}^3$ ) as function of relative root depth. In case of drought stress according to Feddes et al. (1978), relative root density (-) is sufficient.

### 7.8.3 Detailed crop module

Input of the detailed crop module has been divided in 13 parts:

1. Crop factor of crop height
2. Crop development
3. Initial values
4. Green surface area
5. Assimilation
6. Conversion of assimilates into biomass
7. Maintenance respiration
8. Partitioning
9. Death rates
10. Crop water use
11. Salt stress
12. Interception
13. Root growth and root density profile

An example of the input file is given in Box 7.3. In general the theoretic description in Section 7.3 in combination with the descriptions in the input file will be sufficient to guide the model user. However a few additional remarks should be made here.

In part 1 a choice should be made between input of crop factors or crop heights. Crop factors should be used when  $ET_{ref}$  values are used as input, or when the Penman-Monteith method is used to calculate  $ET_{ref}$ . Crop heights should be specified if the potential evapotranspiration fluxes are derived directly for the actual crop (see Table 3.2). In that case also the reflection coefficient and stomatal resistance of the crop should be defined.

In part 8 the user should specify the partitioning factors as function of crop development stage. As explained in Section 7.3.7, WOFOST first divides the gross dry matter among roots and shoots (leaves, stems and storage organs together), using the partitioning factor for roots. Next WOFOST divides the gross dry matter directed to the shoots among leaves, stems and storage organs, using the partitioning factors for these plant organs. At any development stage the sum  $\xi_{leaf} + \xi_{stem} + \xi_{stor}$  must equal one.

The theoretical background of Parts 10-12 (Crop water use, Salt stress and Interception) applies to both the simple and detailed crop model and has been explained earlier.

Boons-Prins et al. (1993) documented specific parameters for the crops winter wheat, grain maize, spring barley, rice, sugar beet, potato, field bean, soy bean, winter oilseed rape and sunflower. WOFOST input files for some crops will be provided with the SWAP program.

# 8 Solute transport

## 8.1 Introduction

Water is a great dissolver and many solutes enter the natural soil system at the Earth surface. The solute residence time in the unsaturated zone is important for soil- and groundwater pollution management. For instance organic compounds are mainly decomposed in the unsaturated zone, where the biological activity is concentrated. Most plants are able to extract water and nutrients from the soil only in the unsaturated zone. In irrigated areas, the long term salinity in the root zone will depend on the amount of percolation from the unsaturated zone. Whereas in the unsaturated zone the transport of solutes is predominantly vertical, once being in the groundwater solutes may diverge in any direction, threatening surface waters, nature reserves and drinking wells. Using an analytical model, Beltman et al. (1995) show the importance of the transport processes in the unsaturated zone as compared to the transport processes in the saturated zone. It is clear that a thorough understanding is needed of the processes that govern the transport, adsorption, root uptake and decomposition of the solutes in the unsaturated zone, in order to analyse and manage soil and water related environmental problems.

SWAP is designed to simulate basic transport processes at field scale level. Although for management purposes most farmers try to have more or less the same soil and drainage condition per field, still the existing soil spatial heterogeneity within a field may cause a large variation of solute fluxes (Biggar and Nielsen, 1976; Van de Pol et al., 1977; Van der Zee and Van Riemsdijk, 1987). Most of this variation is caused by spatial variation of the soil hydraulic functions, preferential flow due to macropores in structured soils or unstable wetting fronts in unstructured soils. In many cases it will not be possible to determine the variation (including the correlations) of all the physical parameters (Hopmans and Stricker, 1989). SWAP confines to the physical processes in order to be flexible in parameter input and allow the simulation of all kind of design and management scenarios. The spatial variability can be taken into account by inverse modelling or Monte Carlo simulation. Inverse modelling has been applied by Groen (1997). He measured for a period of time the solute concentrations in the soil profile and drainage water and determined 'field effective' transport parameters by inverse modelling. In case of Monte Carlo simulations the model is run a large number of times, while the input parameters and boundary conditions are varied according to the variation at comparable fields (Boesten and Van der Linden, 1991).

SWAP focuses on the transport of salts, pesticides and other solutes that can be described with relatively simple physical relations: convection, diffusion, dispersion, root uptake, Freundlich adsorption and first order decomposition. Transport related processes that are not considered in SWAP are:

- volatilization and gas transport
- transport of non-mixing or immiscible fluids (e.g. oil and water)
- chemical equilibria of various solutes (e.g. between  $\text{Na}^+$ ,  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ )
- chemical and biological chain reactions (e.g. mineralization, nitrification)

In case of advanced pesticide transport, including volatilization and kinetic adsorption, SWAP can be used in combination with the model PESTLA (Van den Berg and Boesten, 1998) and PEARL (Leistra et al., 2000; Tiktak et al., 2000). For nutrient transport (nitrogen and phosphorus), SWAP can be used in combination with the model ANIMO (Rijtema et al., 1997; Kroes and Roelsma, 1998) or Soil-N (Groenendijk et al., 2017).

In this chapter, we first describe the solute transport processes that are considered in SWAP. Next, we discuss the boundary conditions applied. Also, we consider how SWAP deals with solute transport in water repellent soils and in cracked clay soils. Salinization is a special case of solute transport. We describe the salinity stress options in SWAP. Finally we provide an overview of solute transport input data.

## 8.2 Basic equations

### 8.2.1 Transport processes

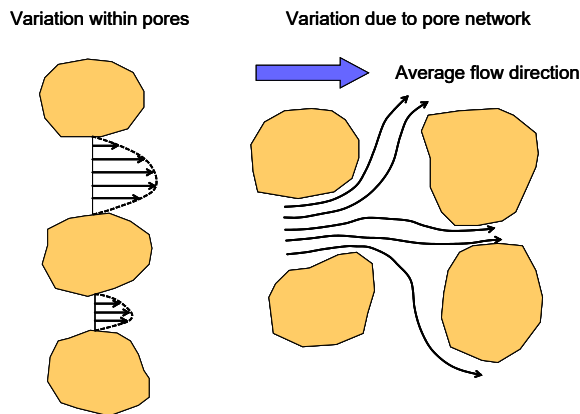

The three main solute transport mechanisms in soil water are diffusion, convection and dispersion. *Diffusion* is solute transport caused by the solute gradient. Thermal motion of the solute molecules within the soil solution causes a net transport of molecules from high to low concentrations. The solute flux  $J_{\text{dif}}$  ( $\text{mg cm}^{-2} \text{d}^{-1}$ ) is generally described by Fick's first law:

$$J_{\text{dif}} = -\theta D_{\text{dif}} \frac{\partial c}{\partial z} \quad (8.1)$$

with  $D_{\text{dif}}$  the diffusion coefficient ( $\text{cm}^2 \text{d}^{-1}$ ) and  $c$  the solute concentration in soil water ( $\text{mg cm}^{-3}$ ).  $D_{\text{dif}}$  is very sensitive to the actual water content, as it strongly affects the solute transport path and the effective cross-sectional transport area. In SWAP we employ the relation proposed by Millington and Quirk (1961):

$$D_{\text{dif}} = D_w \frac{\theta^{7/3}}{\phi_{\text{por}}^2} \quad (8.2)$$

with  $D_w$  the solute diffusion coefficient in free water ( $\text{cm}^2 \text{d}^{-1}$ ) and  $\phi_{\text{por}}$  the soil porosity ( $\text{cm}^3 \text{cm}^{-3}$ ).

**Figure 8.1** Flow velocity variation within pores and within the pore network.

The bulk transport of solutes occurs when solutes are carried along with the moving soil water. The mean flux of this transport is called the *convective* flux,  $J_{\text{con}}$  ( $\text{mg cm}^{-2} \text{d}^{-1}$ ), and can be calculated from the average soil water flux:

$$J_{\text{con}} = qc \quad (8.3)$$

When describing water flow, we usually consider the Darcy flux  $q$  ( $\text{cm d}^{-1}$ ), which is averaged over a certain cross section. In case of solute transport, we have to account for the water velocity variation between pores of different size and geometry and also the water velocity variation inside a pore itself (Figure 8.1). The variety of water velocities cause some solutes to advance faster than the average solute front, and other solutes to advance slower. The overall effect will be that steep solute fronts tends to smoothen or to disperse. Solute fronts seem to flow from high to low concentrations. If the time required for solutes to mix in the transverse direction is small, compared to the time required for solutes to move in the flow direction by mean convection, the *dispersion* flux  $J_{\text{dis}}$  ( $\text{mg cm}^{-2} \text{d}^{-1}$ ) is proportional to the solute gradient (Bear, 1972):

$$J_{\text{dis}} = -\theta D_{\text{dis}} \frac{\partial c}{\partial z} \quad (8.4)$$

with  $D_{\text{dis}}$  the dispersion coefficient ( $\text{cm}^2 \text{d}^{-1}$ ). Under laminar flow conditions  $D_{\text{dis}}$  itself is proportional to the pore water velocity  $v = q/\theta$  (Bolt, 1979):

$$D_{\text{dis}} = L_{\text{dis}} |v| \quad (8.5)$$

with  $L_{\text{dis}}$  the dispersion length (cm). Unless water is flowing very slowly through repacked soil, the dispersion flux is usually much larger than the diffusion flux.

The total solute flux  $J$  ( $\text{mg cm}^{-2} \text{d}^{-1}$ ) is therefore described by:

$$J = J_{\text{con}} + J_{\text{dif}} + J_{\text{dis}} = qc - \theta(D_{\text{dif}} + D_{\text{dis}}) \frac{\partial c}{\partial z} \quad (8.6)$$

## 8.2.2 Continuity and transport equation

By considering conservation of mass in an elementary volume, we may derive the continuity equation for solute transport:

$$\frac{\partial X}{\partial t} = -\frac{\partial J}{\partial z} - S_s \quad (8.7)$$

with  $X$  being the total solute concentration system ( $\text{mg cm}^{-3}$  soil) and  $S_s$  the solute sink term ( $\text{mg cm}^{-3} \text{d}^{-1}$ ) accounting for decomposition and uptake by roots.

The solutes may be dissolved in the soil water or may be adsorbed to organic matter or to clay minerals:

$$X = \theta c + \rho_b Q \quad (8.8)$$

with  $\rho_b$  being the dry soil bulk density ( $\text{g cm}^{-3}$ ) and  $Q$  the amount adsorbed ( $\text{mg g}^{-1}$ ). The adsorption isotherm describes the amount of solutes adsorbed in equilibrium with the dissolved concentration. At this stage we will assume instantaneous equilibrium between  $c$  and  $Q$  and use the non-linear Freundlich equation, which is a flexible function for many organic and inorganic solutes. Freundlich adsorption can be written as:

$$Q = K_f c_{\text{ref}} \left( \frac{c}{c_{\text{ref}}} \right)^{N_f} \quad (8.9)$$

with  $K_f$  the Freundlich coefficient ( $\text{cm}^3 \text{mg}^{-1}$ ),  $N_f$  is the Freundlich exponent (-) and  $c_{\text{ref}}$  is a reference value of the solute concentration ( $\text{mg cm}^{-3}$ ) which is used to make  $N_f$  dimensionless.

The solute sink term  $S_s$  can be written as:

$$S_s = \mu(\theta c + \rho_b Q) + K_r S c \quad (8.10)$$

where  $\mu$  is the first order rate coefficient of transformation ( $\text{d}^{-1}$ ),  $K_r$  is the root uptake preference factor (-) and  $S$  the root water extraction rate ( $\text{d}^{-1}$ ). At the right hand side of Eq. (8.10), the first term accounts for linear decomposition and the second term for root uptake proportional to water uptake.  $K_r$  accounts for positive or negative selection of solute ions relative to the amount of soil water that is extracted.

The coefficient  $\mu$  is affected by soil temperature, water content and depth. Analogous to Boesten and Van der Linden (1991), SWAP calculates  $\mu$  from:

$$\mu = f_T f_\theta f_z \mu_{\text{ref}} \quad (8.11)$$

in which  $f_T$  is a soil temperature factor (-),  $f_\theta$  and  $f_z$  are reduction factors (-) accounting for the effect of soil water content and soil depth, and  $\mu_{\text{ref}}$  ( $\text{d}^{-1}$ ) is  $\mu$  at reference conditions (e.g. soil from the plough layer at 20 °C and at soil water pressure head  $h = -100$  cm).

The factor  $f_T$  is described according to Boesten (1986) as:

$$f_T = e^{\gamma_T(T-20)} \quad (8.12)$$

where  $\gamma_T$  is a parameter ( $^{\circ}\text{C}^{-1}$ ), and  $T$  is the soil temperature in  $^{\circ}\text{C}$ .

Wolfe et al. (1990) describe the importance of the water content in transformation processes. Realizing that it is a large simplification, in SWAP we adopt the relation as proposed by Walker (1974):

$$f_\theta = \left( \frac{\theta}{\theta_{\text{ref}}} \right)^B \quad \text{with} \quad f_\theta \leq 1.0 \quad (8.13)$$

where  $\theta_{\text{ref}}$  is  $\theta$  at  $h = -100$  cm and  $B$  is a constant (-).

The transformation reduction factor for soil depth,  $f_z$ , should be derived from in situ measurements. The user may specify  $f_z$  as function of soil depth in the input file.

Combination of Eq. (8.6), (8.7), (8.8), and (8.10), yields the transport equation applied in SWAP which is valid for dynamic, one-dimensional, convective-dispersive mass transport, including non-linear adsorption, linear decay and proportional root uptake in unsaturated/saturated soil (Van Genuchten and Cleary, 1979; Nielsen et al., 1986; Boesten and Van der Linden, 1991):

$$\frac{\partial(\theta c + \rho_b Q)}{\partial t} = -\frac{\partial(qc)}{\partial z} + \frac{\partial \left[ \theta (D_{\text{dif}} + D_{\text{dis}}) \frac{\partial c}{\partial z} \right]}{\partial z} - \mu(\theta c + \rho_b Q) - K_r S c \quad (8.14)$$

An explicit, central finite difference scheme is used to solve Eq. (8.14):

$$\begin{aligned} & \frac{\theta_i^{j+1} c_i^{j+1} + \rho_b Q_i^{j+1} - \theta_i^j c_i^j - \rho_b Q_i^j}{\Delta t^j} = \\ & \frac{q_{i-1/2}^j c_{i-1/2}^j - q_{i+1/2}^j c_{i+1/2}^j}{\Delta z_i} + \frac{1}{\Delta z_i} \left[ \frac{\theta_{i-1/2}^j D_{i-1/2}^j (c_{i-1}^j - c_i^j)}{1/2(\Delta z_{i-1} + \Delta z_i)} - \frac{\theta_{i+1/2}^j D_{i+1/2}^j (c_i^j - c_{i+1}^j)}{1/2(\Delta z_i + \Delta z_{i+1})} \right] - \\ & \mu_i^j (\theta_i^j c_i^j + \rho_b Q_i^j) - K_r S_i^j c_i^j \end{aligned} \quad (8.15)$$

where  $D (= D_{\text{dif}} + D_{\text{dis}})$  is the overall dispersion coefficient ( $\text{cm}^2 \text{d}^{-1}$ ); the superscript  $j$  denotes the time level, subscript  $i$  the node number and subscripts  $i-1/2$  and  $i+1/2$  refer to linearly interpolated values at the upper and lower compartment boundary, respectively. Compared to an implicit, iterative scheme, above explicit scheme has the advantage that incorporation of non-linear adsorption, mobile/immobile concepts, and other non-linear processes is relatively easy. In order to ensure stability of the explicit scheme, the time step  $\Delta t^j$  should meet the criterium (Van Genuchten and Wierenga, 1974; corresponding to the Fourier number being  $< 0.5$ ):

$$\Delta t^j \leq \frac{\Delta z_i^2 \theta_i^j}{2D_i^j} \quad (8.16)$$

This stability criterium applies to non-sorbing substances and is therefore also safe for sorbing substances.

### 8.3 Boundary conditions

As *initial condition*, the user needs to specify the solute concentrations  $c_i$  ( $\text{mg cm}^{-3}$  soil water) at different soil depths.

For the *top boundary condition*, the solute concentrations in irrigation and rain water,  $c_{\text{irr}}$  and  $c_{\text{prec}}$  ( $\text{mg cm}^{-3}$ ), need to be specified. During evaporation no solutes leave the soil profile at the surface. During infiltration, the solute concentration of water that enters the soil profile at the top,  $c_{\text{pond}}$

( $\text{mg cm}^{-3}$ ), is affected by the ponding layer and its concentration at the former time step, the solute amounts coming in by rain and irrigation, and the solute amounts transported laterally to cracks:

$$c_{\text{pond}}^j = \frac{(P_{\text{net}}^j c_{\text{prec}} + I_{\text{net}}^j c_{\text{irr}}) \Delta t^j + h_{\text{pond}}^{j-1} c_{\text{pond}}^{j-1}}{h_{\text{pond}}^j - (q_{\text{top}} + q_{\text{lat}}) \Delta t^j} \quad (8.17)$$

where  $P_{\text{net}}$  is the net precipitation rate ( $\text{cm d}^{-1}$ ),  $I_{\text{net}}$  is the net irrigation rate ( $\text{cm d}^{-1}$ ),  $h_{\text{pond}}$  is the height of water ponding on the soil surface,  $q_{\text{top}}$  is the water flux at the soil surface ( $\text{cm d}^{-1}$ , positive upward) and  $q_{\text{lat}}$  is the water flux flowing to cracks ( $\text{cm d}^{-1}$ , see Section 8.4). The solute flux  $J_{\text{top}}$  ( $\text{mg cm}^{-2}$ ) entering the soil at the surface, equals:

$$J_{\text{top}} = q_{\text{top}} c_{\text{pond}} (1.0 - A_c) \quad (8.18)$$

where  $A_c$  is the relative crack area ( $\text{cm}^2 \text{cm}^{-2}$ ).

For the *drainage boundary condition*, during drainage ( $q_{\text{drain}} > 0$ ) the solute flux  $J_{\text{drain}}$  ( $\text{mg cm}^{-2}$ ) that leaves the one-dimensional soil profile is accumulated for each compartment below groundwater level:

$$J_{\text{drain}} = \sum_{i=n_{\text{gw}}}^n q_{\text{drain},i} c_i \quad (8.19)$$

where  $n_{\text{gw}}$  is the compartment with the groundwater level and  $q_{\text{drain},i}$  is the lateral drainage flux ( $\text{cm d}^{-1}$ ) of compartment  $i$ . During infiltration ( $q_{\text{drain}} < 0$ ),  $J_{\text{drain}}$  follows from:

$$J_{\text{drain}} = \sum_{i=n_{\text{gw}}}^n q_{\text{drain},i} c_{\text{surf}} \quad (8.20)$$

where  $c_{\text{surf}}$  is the solute concentration in surface water ( $\text{mg cm}^{-3}$ ), specified as input.

For the *bottom boundary condition*, SWAP uses the flux through the bottom of the soil profile  $q_{\text{bot}}$  ( $\text{cm d}^{-1}$ ). In case of upward flow ( $q_{\text{bot}} > 0$ ), the solute flux  $J_{\text{bot}}$  ( $\text{mg cm}^{-2}$ , positive is upwards) equals:

$$J_{\text{bot}} = q_{\text{bot}} c_{\text{seep}} \quad (8.21)$$

where  $c_{\text{seep}}$  is the solute concentration in groundwater ( $\text{mg cm}^{-3}$ ) specified as input. This concentration can be specified as constant or variable in time. Also the user may select  $c_{\text{surf}}$  in stead of  $c_{\text{seep}}$ .

If  $q_{\text{bot}}$  is directed downwards ( $q_{\text{bot}} < 0$ ), the solute flux  $J_{\text{bot}}$  ( $\text{mg cm}^{-2}$ ) equals:

$$J_{\text{bot}} = q_{\text{bot}} c_n \quad (8.22)$$

## 8.4 Crack solute transport

In order to calculate solute transport in combination with macropore flow, SWAP may generate soil water fluxes which are input to the pesticide model PEARL or the nutrient model ANIMO.

## 8.5 Residence time in the saturated zone

In the case of heterogeneous groundwater flow or multi-level drainage, the residence time approach described in Chapter 4 is used. This section describes an alternative concept assuming a homogeneous aquifer and field drainage at one level.

Ernst (1973) and Van Ommen (1985) showed that the breakthrough curve of a field with fully penetrating drainage canals, is identical to the breakthrough curve of a reservoir with complete mixing. This is also valid if adsorption can be described by a linear isotherm and transformation occurs proportional to the existing concentration (Van Ommen, 1985).

Linear adsorption might be described by:

$$Q = k_{\text{ads}} c_{\text{gr}} \quad (8.23)$$

where  $k_{\text{ads}}$  is the linear adsorption coefficient in the saturated zone ( $\text{cm}^3 \text{mg}^{-1}$ ). Numerical analysis by Duffy and Lee (1992) showed that dispersion in the saturated zone has only a minor effect for  $L_{\text{drain}}/d_{\text{aquif}} \geq 10$ , where  $L_{\text{drain}}$  is the distance between the drainage canals (cm) and  $d_{\text{aquif}}$  the thickness of the aquifer (cm). Generally  $L_{\text{drain}}/d_{\text{aquif}}$  will be around 10 or larger, therefore SWAP ignores dispersion.

In order to derive the breakthrough curve, the similarity is used between breakthrough curves of drained fields and mixed reservoirs. Starting point is the solute transport equation of the unsaturated zone, Eq. (8.14). Replacement of non-linear adsorption by linear adsorption, and removal of dispersion and root water uptake, results in the mass balance equation of the saturated zone:

$$\frac{\partial(\theta_s c_{\text{gr}} + \rho_b k_{\text{ads}} c_{\text{gr}})}{\partial t} = \frac{q_{\text{drain}}}{d_{\text{aquif}}}(c_{\text{in}} - c_{\text{gr}}) - \mu_{\text{gr}}(\theta_s c_{\text{gr}} + \rho_b k_{\text{ads}} c_{\text{gr}}) \quad (8.24)$$

where  $\theta_s$  is the saturated water content ( $\text{cm}^3 \text{cm}^{-3}$ ),  $q_{\text{drain}}$  is the drainage flux ( $\text{cm d}^{-1}$ ),  $c_{\text{in}}$  is the solute concentration of water percolating from the unsaturated zone ( $\text{mg cm}^{-3}$ ) and  $\mu_{\text{gr}}$  is the first order rate coefficient for transformation in the saturated zone ( $\text{d}^{-1}$ ). Eq. (8.24) applies to a drainage situation ( $q_{\text{drain}} > 0$ ). In case of infiltration ( $q_{\text{drain}} < 0$ ), SWAP assumes the infiltrating water from the drainage system to be solute free, and Eq. (8.24) transforms into:

$$\frac{\partial(\theta_s c_{\text{gr}} + \rho_b k_{\text{ads}} c_{\text{gr}})}{\partial t} = \frac{q_{\text{drain}}}{d_{\text{aquif}}} c_{\text{gr}} - \mu_{\text{gr}}(\theta_s c_{\text{gr}} + \rho_b k_{\text{ads}} c_{\text{gr}}) \quad (8.25)$$

Eq. (8.24) and (8.25) are discretized as an explicit, forward difference scheme. The boundary conditions that apply to the saturated zone, are included in Eq. (8.24) and (8.25).

## 8.6 Salinity stress

Salinity stress reduces the root water uptake and is related to the solute concentration in soil water. Two options are offered in SWAP:

1. Linear reduction function (Maas and Hoffman, 1977)
2. Osmotic head (De Jong van Lier et al., 2009)

Figure 8.2 shows the reduction function of Maas and Hoffman (1977). The reduction of root water uptake ( $\alpha_{\text{rs}}$ ) when the salt concentration exceeds a threshold value is linearly related to the salinity concentration:

$$\alpha_{\text{rs}} = 1.0 - (c - S_{\text{max}}) S_{\text{slope}}$$

where  $c$  is the salinity concentration ( $\text{mg cm}^{-3}$ ),  $S_{\text{max}}$  is the salinity threshold value ( $\text{mg cm}^{-3}$ ) and  $S_{\text{slope}}$  is the decline of the root water uptake factor per unit increase of salinity concentration ( $\text{cm}^3 \text{mg}^{-1}$ ).

**Figure 8.2** Reduction coefficient for root water uptake,  $\alpha_{\text{rs}}$ , as function of soil water salinity concentration (after Maas and Hoffman, 1977).

De Jong van Lier et al. (2009) demonstrated how the osmotic head due to salts in soil water can be included in microscopic root water uptake. To apply this concept for salinity stress, the root water uptake under dry conditions should be based on the microscopic approach (see Par. 3.5.4). Mind that if salinity stress is based on osmotic head, toxic effects of salts are not included. The application of the osmotic head requires tuning of the drought input parameters of the crop input file. Currently this option is advised for specialists only.

## 8.7 Groundwater age

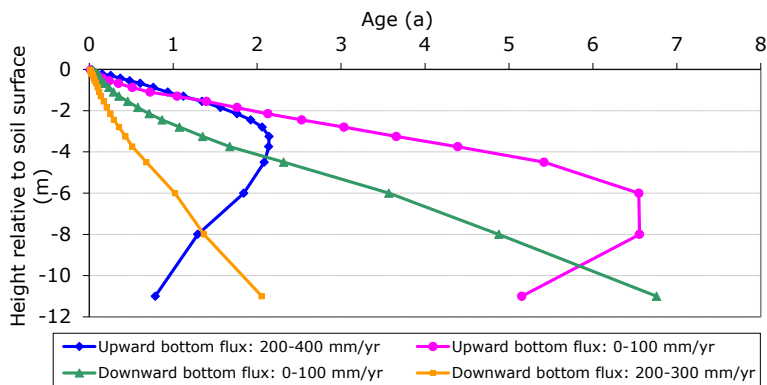

Soil moisture and groundwater age can be calculated as the time elapsed after entering the soil water domain described by the SWAP model. Following the method used by Goode (1996) and Lemieux and Sudicky (2010), the soil moisture age is governed by a convection-dispersion equation for an inert solute with an internal source of unit (1) strength:

$$\frac{\partial \theta A}{\partial t} = -\frac{\partial}{\partial z} q_z A + \frac{\partial}{\partial z} \left( \theta D \frac{\partial A}{\partial z} \right) - SA + \theta \quad (8.26)$$

where  $A$  is the average age of water particles in a package of water (d).

The age of water entering the model boundaries is set to 0, irrespective of the boundary type. In soil profiles exposed to a constant upward flux at the bottom boundary, the age at the bottom equals zero and the distribution with depth shows a curved course.

The capabilities of the age module implemented in the SWAP model is illustrated in Figure 8.3. It shows the long term averaged age distribution with depth for four classes of hydrological plots in the Dutch Nationwide STONE model (Groenendijk et al, 2013).

**Figure 8.3** Age is a function of depth for different classes of hydrological plots in the Dutch nationwide STONE model (Groenendijk et al, 2013).

The age of soil water in the profiles with a relative low leaching rate ( $0-100 \text{ mm yr}^{-1}$ ) is higher than in the profiles with a relative high leaching rate ( $200-300 \text{ mm yr}^{-1}$ ) and the age in the profiles with a relative low upward seepage ( $0-100 \text{ mm yr}^{-1}$ ) is higher than in the profiles with a relative high upward seepage rate rate ( $200-400 \text{ mm yr}^{-1}$ ). The position of the maximum age in the profiles with upward seepage depends on the seepage flow rate and the lay-out of the drainage systems.

---

## 8.8 User instructions

Box 8.1 lists the input data for solute transport, which are divided over the parts:

1. Main switch
2. Top and initial boundary condition
3. Miscellaneous parameters as function of soil depth
4. Diffusion coefficient and solute uptake by roots
5. Adsorption
6. Decomposition
7. Solute residence in the saturated zone
8. Soil moisture and groundwater age

In general the theoretic description in Sections 8.2 – 8.6 in combination with the descriptions in the input file will be sufficient to guide the model user. A few additional remarks are appropriate at this place.

In case conservative solute are simulated, like salts are non-reactive tracers, we need only to consider the transport processes convection, diffusion, dispersion and passive uptake by plant roots.

At most field conditions we may neglect the effect of diffusion with respect to dispersion and therefore may specify  $D_{dif} = 0$ . The parameter dispersion length,  $L_{dis}$  (cm), depends on the scale over which the water flux and solute convection are averaged. Typical values of  $L_{dis}$  are 0.5 - 2.0 cm in packed laboratory columns and 5-20 cm in the field (Jury et al., 1991; Vanderborght and Vereecken, 2007).

SWAP supports two methods to account for the residence time of solutes in the saturated zone. The first one by proper distribution of the lateral drainage flux over the saturated compartments (Chapter 4). In that case we may set  $SWBR = 0$  and specify the solute concentration in the groundwater as boundary condition for upward flow (Box 8.1, Part 7). The second method has been described in this chapter and views the saturated zone as one mixed reservoir (Section 8.5). In that case we should set  $SWBR = 1$  and provide the effective transport properties of the saturated zone (Box 8.1, Part 7).

The input data for salinity stress depend on the plant specie and are listed in the crop input file. SWAP input data for the Maas and Hoffman reduction function are listed in Appendix 9.

To simulate soil moisture and groundwater age the user should add a flag to the section for solute transport (Box 8.1, Part 8). When this flag (flAgeTracer) is set with the value .TRUE. the model will automatically produce 2 output files: i) result.ageeffluent.csv and ii) Result.ageProfile.csv with groundwater age (d) of respectively effluent and soil water.

## 9 Soil temperature

Soil temperature affects many physical, chemical and biological processes in the top soil, for instance the surface energy balance, soil hydraulic properties, decomposition rate of solutes and growth rate of roots. Currently, SWAP uses soil temperature in the following processes:

- suppression of grass growth due to low temperatures
- reduction of hydraulic conductivity and root water uptake at low temperatures
- mineralization rate
- respiration rate (and some other oxygen related processes)
- solute decomposition rate

Other temperature relations can be easily included, if needed. SWAP calculates the soil temperatures either analytically or numerically. In the following sections the heat flow equations and the applied analytical and numerical solutions are discussed.

### 9.1 Temperature conductance equation

If we consider heat transport only by convection, the one-dimensional soil heat flux,  $q_{\text{heat}}$  ( $\text{J cm}^{-2} \text{d}^{-1}$ ), can be described as:

$$q_{\text{heat}} = -\lambda_{\text{heat}} \frac{\partial T}{\partial z} \quad (9.1)$$

where  $\lambda_{\text{heat}}$  is the thermal conductivity ( $\text{J cm}^{-1} \text{ }^\circ\text{C}^{-1} \text{d}^{-1}$ ) and  $T$  is the soil temperature ( $^\circ\text{C}$ ).

Conservation of energy results in:

$$C_{\text{heat}} \frac{\partial T}{\partial t} = \frac{-\partial q_{\text{heat}}}{\partial z} \quad (9.2)$$

where  $C_{\text{heat}}$  is the soil heat capacity ( $\text{J cm}^{-3} \text{ }^\circ\text{C}^{-1}$ ).

Combination of Eq. (9.1) and (9.2) yields the differential equation for soil heat flow:

$$C_{\text{heat}} \frac{\partial T}{\partial t} = \frac{\partial \left( \lambda_{\text{heat}} \frac{\partial T}{\partial z} \right)}{\partial z} \quad (9.3)$$

In general in the liquid phase, radiation and convection will also transport heat. As the contribution of radiation and convection to soil heat transport in general is small compared to conductance (e.g. Moene and van Dam, 2014), SWAP only considers conductance. In the vapour phase, diffusion may contribute to soil heat transport. The rate of heat transfer by water vapour diffusion is small and proportional to the temperature gradient (De Vries, 1975). Therefore, such diffusion can be taken into account by slightly increasing the soil thermal diffusivity. This approach is followed in SWAP as well. Apparent thermal properties rather than real thermal properties are assumed to account for both conductive and non-conductive heat flow.

## 9.2 Numerical solution

The parameters  $\lambda_{\text{heat}}$  and  $C_{\text{heat}}$  strongly depend on the soil moisture content. Therefore in general Eq. (9.3) can only be solved with a numerical solution. SWAP employs a fully implicit finite difference numerical scheme to solve Eq. (9.3):

$$C_i^{j+1} (T_i^{j+1} - T_i^j) = \frac{\Delta t^j}{\Delta z_i} \left[ \lambda_{i-1/2}^{j+1/2} \frac{T_{i-1}^{j+1} - T_i^{j+1}}{\Delta z_u} - \lambda_{i+1/2}^{j+1/2} \frac{T_i^{j+1} - T_{i+1}^{j+1}}{\Delta z_\ell} \right] \quad (9.4)$$

where superscript  $j$  denotes the time level, subscript  $i$  is the node number,  $\Delta z_u = z_{i-1} - z_i$  and  $\Delta z_\ell = z_i - z_{i+1}$ . As the coefficients  $C_{\text{heat}}$  and  $\lambda_{\text{heat}}$  are not affected by the soil temperature itself, Eq. (9.4) is a linear equation.

Both  $C_{\text{heat}}$  and  $\lambda_{\text{heat}}$  depend on the soil composition. The volumetric heat capacity is calculated as weighted mean of the heat capacities of the individual components (De Vries, 1963):

$$C_{\text{heat}} = f_{\text{sand}} C_{\text{sand}} + f_{\text{clay}} C_{\text{clay}} + f_{\text{organic}} C_{\text{organic}} + \theta C_{\text{water}} + f_{\text{air}} C_{\text{air}} \quad (9.5)$$

where  $f$  and  $C$  on the right hand side of Eq. (9.4) are the volume fraction ( $\text{cm}^3 \text{cm}^{-3}$ ) and volumetric heat capacity ( $\text{J cm}^{-3} \text{ }^\circ\text{C}^{-1}$ ) of each component, respectively, and the components are indicated in the subscripts. Table 9.1 gives values of  $C$  for the different soil components.

**Table 9.1** Volumetric heat capacity and thermal conductivity of the soil components.

Component	Volumetric heat capacity, $C_{\text{heat}}$ ( $\text{J cm}^{-3} \text{ }^\circ\text{C}^{-1}$ )	Thermal conductivity, $\lambda_{\text{heat}}$ ( $\text{J cm}^{-1} \text{ }^\circ\text{C}^{-1} \text{ d}^{-1}$ )
Sand	2.128	7603
Clay	2.385	2523
Organic	2.496	216
Water	4.180	492
Air (20°C)	0.001212	variable

In order to calculate  $C_{\text{heat}}$  from (9.5), the percentage (by volume) of sand and clay, denoted  $VP_{\text{sand}}$  and  $VP_{\text{clay}}$ , respectively, must be specified by the SWAP user.  $VP_{\text{sand}}$  and  $VP_{\text{clay}}$  should be provided as percentages of the total *solid* soil matter and may differ for each soil layer. The total volume fraction of solid matter is given by:

$$\theta_{\text{solid}} = 1 - \theta_{\text{sat}} \quad (9.6)$$

where  $\theta_{\text{sat}}$  is the saturated volumetric water content. The volume fraction of air is equal to the saturated minus the actual water content:

$$f_{\text{air}} = \theta_{\text{sat}} - \theta \quad (9.7)$$

$f_{\text{sand}}$ ,  $f_{\text{clay}}$  and  $f_{\text{organic}}$  are then calculated by:

$$f_{\text{sand}} = \frac{VP_{\text{sand}}}{100} \theta_{\text{solid}} \quad (9.8)$$

$$f_{\text{clay}} = \frac{VP_{\text{clay}}}{100} \theta_{\text{solid}} \quad (9.9)$$

$$f_{\text{organic}} = \theta_{\text{solid}} - f_{\text{sand}} - f_{\text{clay}} \quad (9.10)$$

where it has been assumed that solid matter that is not sand or clay, is organic.

Table 9.1 also lists the thermal conductivities, which are largest for sand and clay, an order smaller for organic material and water, and again an order smaller for air. Hence the space-average thermal

conductivity of a soil depends upon its mineral composition and organic matter content, as well as the volume fractions of water and air. Since the thermal conductivity of air is much smaller than that of water or solid matter, a high air content (or low water content) corresponds to a low thermal conductivity.

The components that affect  $\lambda_{\text{heat}}$  are the same as those affecting  $C_{\text{heat}}$ . However, the variation in  $\lambda_{\text{heat}}$  is much greater than the variation of  $C_{\text{heat}}$ . In the range of soil wetness normally experienced in the field,  $C_{\text{heat}}$  may undergo a threefold or fourfold change, whereas the corresponding change in  $\lambda_{\text{heat}}$  may be hundredfold or more. Unlike heat capacity, thermal conductivity is also sensitive to the sizes, shapes, and spatial arrangements of the soil particles (Hillel, 1980).

The thermal conductivity is found by considering the soil as a continuous liquid or gaseous phase in which soil and respectively gas or liquid 'particles' are dispersed. In the case of a 'wet' soil ( $\theta > \theta_{\text{wet}}$ ) liquid water is assumed to be the continuous phase and the thermal conductivity is given by:

$$\lambda_{\text{heat}} = \frac{x_{\text{sand-water}} f_{\text{sand}} \lambda_{\text{sand}} + x_{\text{clay-water}} f_{\text{clay}} \lambda_{\text{clay}} + x_{\text{organic-water}} f_{\text{organic}} \lambda_{\text{organic}} + x_{\text{water-water}} \theta \lambda_{\text{water}} + x_{\text{air-water}} f_{\text{air}} \lambda_{\text{air}}}{x_{\text{sand-water}} f_{\text{sand}} + x_{\text{clay-water}} f_{\text{clay}} + x_{\text{organic-water}} f_{\text{organic}} + x_{\text{water-water}} \theta + x_{\text{air-water}} f_{\text{air}}} \quad (9.11)$$

The  $\lambda$ -values on the right hand side of Eq. (9.11) refer to the thermal conductivities ( $\text{J cm}^{-1} \text{ } ^\circ\text{C}^{-1} \text{ d}^{-1}$ ) of each individual component, as listed in Table 9.1. The weighting factors  $x_{mn}$  for component  $m$  particles suspended in the continuous phase  $n$  phase depend on the ratio of the specific thermal conductivities of component  $m$  and  $n$  and on the shape of  $m$  particles in the direction of the temperature gradient. When we assume the particles to be spheroids whose axes are randomly oriented in the soil (Ten Berge, 1986), the weighting factors can be calculated by:

$$x_{mn} = \frac{0.66}{1 + g_m (\lambda_m / \lambda_n - 1)} + \frac{0.33}{1 + (\lambda_m / \lambda_n - 1)(1 - 2g_m)} \quad (9.12)$$

The shape factors and weights calculated using Eq. (9.12) are given in Table 9.2. The thermal conductivity is quite sensitive to the air shape factor ( $g_a$ ), which appears to depend on the air content itself and is calculated as:

$$\text{in wet soils } (\theta > \theta_{\text{wet}}): \quad g_a = 0.333 - \frac{\theta_{\text{sat}} - \theta}{\theta_{\text{sat}}} (0.333 - 0.035) \quad (9.13)$$

$$\text{in dry soils } (\theta < \theta_{\text{dry}}): \quad g_a = 0.013 + \frac{\theta}{\theta_{\text{dry}}} (g_{a,\text{dry}} - 0.013) \quad (9.14)$$

where  $g_{a,\text{dry}}$  is the value of Eq. (9.13) at  $\theta = \theta_{\text{dry}}$ . In this way  $g_a$  varies between 0.013 ( $\theta = 0$ ) and 0.333 ( $\theta = \theta_{\text{sat}}$ ).

For 'dry' soil ( $\theta < \theta_{\text{dry}}$ ) air is considered as the continuous phase and the conductivity is given by:

$$\lambda_{\text{heat}} = 1.25 \frac{x_{\text{sand-air}} f_{\text{sand}} \lambda_{\text{sand}} + x_{\text{clay-air}} f_{\text{clay}} \lambda_{\text{clay}} + x_{\text{organic-air}} f_{\text{organic}} \lambda_{\text{organic}} + x_{\text{water-air}} \theta \lambda_{\text{water}} + x_{\text{air-air}} f_{\text{air}} \lambda_{\text{air}}}{x_{\text{sand-air}} f_{\text{sand}} + x_{\text{clay-air}} f_{\text{clay}} + x_{\text{organic-air}} f_{\text{organic}} + x_{\text{water-air}} \theta + x_{\text{air-air}} f_{\text{air}}} \quad (9.15)$$

which is similar to Eq. (9.11) with an empirical correction factor (Ten Berge, 1986).

In the case that neither water nor air can be considered as the continuous phase ( $\theta_{\text{dry}} < \theta < \theta_{\text{wet}}$ )  $\lambda_{\text{heat}}$  is found by interpolation between values at the wet and dry limits:

$$\lambda_{\text{heat}}(\theta) = \lambda_{\text{heat}}(\theta_{\text{dry}}) + \frac{\lambda_{\text{heat}}(\theta_{\text{wet}}) - \lambda_{\text{heat}}(\theta_{\text{dry}})}{\theta_{\text{wet}} - \theta_{\text{dry}}} (\theta - \theta_{\text{dry}}) \quad (9.16)$$

The values of  $\theta_{\text{dry}}$  and  $\theta_{\text{wet}}$  are taken as  $0.02$  and  $0.05 \text{ cm}^3 \text{ cm}^{-3}$ , respectively. We refer to De Vries (1975), Ten Berge (1986) and Moene and Van Dam (2014) for more information on the calculation of  $\lambda_{\text{heat}}$ .

**Table 9.2** Shape and weight factors for different components in water and air phases, as used for thermal conductivity calculations (Ashby et al., 1996).

	Component				
	Sand	Clay	Organic	Water	Air
Shape factor	$g_{\text{sand}}$ 0.14	$g_{\text{clay}}$ 0.125	$g_{\text{organic}}$ 0.50	$g_{\text{water}}$ 0.14	$g_{\text{air}}$ Eq. (9.13)
Weight factor for water as continuous phase	$x_{\text{sand-water}}$ 0.2461	$x_{\text{clay-water}}$ 0.7317	$x_{\text{organic-water}}$ 1.2602	$x_{\text{water-water}}$ 1.0000	$x_{\text{air-water}}$ 1.6062
Weight factor for air as continuous phase	$x_{\text{sand-air}}$ 0.0143	$x_{\text{clay-air}}$ 0.6695	$x_{\text{organic-air}}$ 0.4545	$x_{\text{water-air}}$ 0.1812	$x_{\text{air-air}}$ 1.0000

At the soil surface either the daily average air temperature  $T_{\text{avg}}$  or measured soil surface temperatures can be used as a boundary condition. In case of a snow layer and the use of  $T_{\text{avg}}$ , SWAP will adjust  $T_{\text{avg}}$  as described in Chapter 10. At the bottom of the soil profile either soil temperatures can be specified or  $q_{\text{heat}} = 0.0$  can be selected. The latter option is valid for large soil columns.

Application of Eq. (9.4) to each node and including the boundary conditions at the top and bottom of the soil profile, results in a tri-diagonal system of equations, as shown in Appendix 6. SWAP solves the equations with  $LU$ -decomposition for tridiagonal systems (Press et al., 1989).

### 9.3 Analytical solution

If the values of  $\lambda_{\text{heat}}$  and  $C_{\text{heat}}$  are considered to be constant within the discretized soil layer and time interval, the soil thermal diffusivity  $D_{\text{heat}}$  ( $\text{cm}^2 \text{d}^{-1}$ ) can be defined as:

$$D_{\text{heat}} = \frac{\lambda_{\text{heat}}}{C_{\text{heat}}} \quad (9.17)$$

and Eq. (9.3) simplifies to:

$$\frac{\partial T}{\partial t} = D_{\text{heat}} \frac{\partial^2 T}{\partial z^2} \quad (9.18)$$

This partial differential equation can be solved for simple boundary conditions, assuming  $D_{\text{heat}}$  constant or very simple functions for  $D_{\text{heat}}$  (Van Wijk, 1966; Feddes, 1971; Wesseling, 1987). A commonly used top boundary condition is a sinusoidally varying soil surface temperature:

$$T(0, t) = T_{\text{mean}} + T_{\text{ampl}} \sin\left(\frac{1}{2}\pi + \omega(t - t_{\text{max}})\right) \quad (9.19)$$

where  $T_{\text{mean}}$  is the mean yearly temperature ( $^{\circ}\text{C}$ ),  $T_{\text{ampl}}$  is the wave amplitude ( $^{\circ}\text{C}$ ),  $\omega = 2\pi / \tau$  is the angular frequency, where  $\tau$  is the period of the wave (d),  $t$  is time (d) starting January 1<sup>st</sup> and  $t_{\text{max}}$  equals  $t$  when the temperature reaches its maximum. In case of a semi-infinite soil profile with constant  $D_{\text{heat}}$  and using Eq. (9.19), the solution to Eq. (9.18) is:

$$T(z, t) = T_{\text{mean}} + T_{\text{ampl}} e^{\frac{z}{d_{\text{temp}}}} \sin\left(\frac{1}{2}\pi + \omega(t - t_{\text{max}}) + \frac{z}{d_{\text{temp}}}\right) \quad (9.20)$$

where  $d_{\text{temp}}$  is the damping depth (cm), which equals:

$$d_{\text{temp}} = \sqrt{\frac{2D_{\text{heat}}}{\omega}} \quad (9.21)$$

Equation (9.20) can be used for daily or yearly fluctuations. Measured values of  $D_{\text{heat}}$  for various dry and wet soils are given in Table 9.3. Figure 9.1 gives an example of calculated soil temperatures for a dry and wet sand soil. The sinusoidal temperature fluctuations at each depth are reduced in amplitude and delayed in time with respect to the top boundary condition. Although the heat capacity of wet sand is higher than of dry sand, the temperature wave in the wet sand is less attenuated due to the higher thermal conductivity.

**Table 9.3** Thermal diffusivity  $D_{heat}$  ( $cm^2 d^{-1}$ ) for various dry and wet soils (Jury et al., 1991).

Sand		Loam		Clay		Peat	
Dry	Wet	Dry	Wet	Dry	Wet	Dry	Wet
147	380	156	518	156	320	112	104

**Figure 9.1** Calculated soil temperatures at depths  $z = 0$ ,  $z = -5$  en  $z = -10$  cm for a dry (A) and a wet (B) sand soil. The following input data were used:  $T_{mean} = 12$  °C,  $T_{ampli} = 10$  °C,  $\tau = 1$  d,  $t_{max} = 0.5$  d en  $D_{heat} = 147$  (droog) en  $380$  (nat)  $cm^2 d^{-1}$ .

## 9.4 User instructions

Box 9.1 lists the input data for heat transport. When the analytical method is used, the parameters describing the soil surface temperature wave and the damping depth should be specified. The damping depth might be derived from Eq. (9.21) and the thermal diffusivity values from Table 9.3. When the numerical method is used, information should be given of the soil texture, initial soil temperatures and type of bottom boundary condition.

In case top soil temperatures are provided in a separate file ( $SwTopHea = 2$ ), the file TSOILFILE must have the extension .TSS. The files should contain two data columns: the first column (with header DATET) contains the date (dd-mm-yyyy), and the second column (header TTOP) contains the soil surface temperature (°C).

Box 9.1 Information on heat transport in main file \*.SWP.

# 10 Snow and frost

SWAP contains separate switches for simulating snow and frost conditions. When both switches are turned off, in the simulations precipitation and soil water remain unfrozen at temperatures below zero °C. Snow is described in Section 10.1 and frost in Section 10.2.

## 10.1 Snow

When the snow option is switched on, SWAP simulates snowfall, accumulation of snow in a snowpack and the water balance of the snowpack. The present approach is quite simple and consists of the most basic processes, including the insulating effect of snow on energy transport. Simulation of snowfall and water balance of the snowpack is performed on a daily basis. Snowfall and snowpack are described in the next two Sections.

### 10.1.1 Snowfall

Snowfall occurs when air temperature drops below a threshold value. In that case precipitation falls partly or completely as snow. The division of total precipitation  $P$  (cm d<sup>-1</sup>) into snow  $P_s$  (cm d<sup>-1</sup>) and rain  $P_r$  (cm d<sup>-1</sup>) depends on the daily average air temperature. For air temperatures  $T_{av}$  (°C) below the threshold temperature  $T_{snow}$  (°C) all precipitation is snow, while for air temperatures above the threshold temperature  $T_{rain}$  (°C) all precipitation is rain. Between both threshold temperatures the snow fraction  $f_{snow}$  (-) and rain fraction  $f_{rain}$  (-) of the precipitation are obtained by linear interpolation:

$$f_{snow} = 1 \quad \text{for } T_{av} \leq T_{snow} \quad (10.1.a)$$

$$f_{snow} = \frac{T_{rain} - T_{av}}{T_{rain} - T_{snow}} \quad \text{for } T_{snow} < T_{av} < T_{rain} \quad (10.1.b)$$

$$f_{snow} = 0 \quad \text{for } T_{av} \geq T_{rain} \quad (10.1.c)$$

$$f_{rain} = 1 - f_{snow} \quad (10.1.d)$$

$$P_s = f_{snow} P \quad \text{and} \quad P_r = f_{rain} P \quad (10.1.e)$$

### 10.1.2 Snowpack

Snow that falls on the soil surface is accumulated in a snowpack, provided that the soil surface temperature is below 0.5 °C. The water balance of the snowpack includes storage, the incoming fluxes snow and rain and the outgoing fluxes melt and sublimation (Figure 10.1) and reads:

$$S_{snow}^t - S_{snow}^{t-1} = (P_r + P_s - q_{melt} - q_{melt,r} - E_s) \Delta t \quad (10.2)$$

in which  $S_{snow}$  is snow storage at day  $t$  or the previous day  $t-1$  in cm water equivalent (cm w.e.),  $P_s$  and  $P_r$  are the two precipitation terms (cm w.e. d<sup>-1</sup>),  $q_{melt}$  and  $q_{melt,r}$  are two snow melt terms (cm w.e. d<sup>-1</sup>),  $E_s$  is snow sublimation (cm w.e. d<sup>-1</sup>) and  $\Delta t$  is the time step of one day.

**Figure 10.1** Water fluxes to and from the snow layer.

Two forms of snowmelt are included in the model:

1. air temperature rise above a threshold value, according to the 'degree-day model' (Kustas & Rango, 1994):

$$q_{\text{melt}} = a (T_{\text{av}} - T_b) \quad \text{for } T_{\text{av}} > T_b \quad (10.3.a)$$

$$q_{\text{melt}} = 0 \quad \text{for } T_{\text{av}} \leq T_b \quad (10.3.b)$$

where  $a$  is the 'degree-day factor' ( $\text{cm } ^\circ\text{C}^{-1} \text{d}^{-1}$ ),  $T_{\text{av}}$  is the daily average air temperature ( $^\circ\text{C}$ ) and  $T_b$  is the base temperature ( $^\circ\text{C}$ ) which is set to  $0^\circ\text{C}$  according to Kustas & Rango (1994). The value of  $a$  can be specified by the user, and ranges usually between 0.35 and  $0.60 \text{ cm } ^\circ\text{C}^{-1} \text{d}^{-1}$ .

2. heat release from rainfall  $P_r$  on the snowpack: additional melt will occur due to heat released by splashing raindrops. This snowmelt rate  $q_{\text{melt},r}$  is calculated with (Fernández, 1998; Singh et al., 1997):

$$q_{\text{melt},r} = \frac{P_r C_m (T_{\text{av}} - T_{\text{snow}})}{L_f} \quad \text{for } T_{\text{av}} > T_{\text{snow}} \quad (10.4.a)$$

$$q_{\text{melt},r} = 0 \quad \text{for } T_{\text{av}} \leq T_{\text{snow}} \quad (10.4.b)$$

where  $C_m$  is the heat capacity of water ( $4180 \text{ J kg}^{-1} \text{ } ^\circ\text{C}^{-1}$ ),  $L_f$  is the latent heat of fusion ( $333580 \text{ J kg}^{-1}$ ) and  $T_{\text{snow}}$  is the temperature of the snowpack, which is set to  $0^\circ\text{C}$ .

The melt fluxes leave the snow pack as infiltration into the soil and/or runoff when infiltration capacity of the soil is exceeded.

Snow can evaporate directly into the air, a process called sublimation. The sublimation rate  $E_s$  is taken equal to the potential evaporation rate  $E_p$  (see Chapter 3). When a snow pack exists, the evapotranspiration from the soil and vegetation is set to zero.

A snowpack on top of the soil surface has a large impact on soil temperatures. Because of the low thermal conductivity of snow (0.1-0.4 times thermal conductivity of water), a snowpack can form a perfect insulating layer that will considerably dampen the effects of air temperature on soil temperature. The insulating effect of a snowpack on soil temperature is accounted for by calculating the temperature at the soil surface, the driving force for soil temperature calculations (see Chap. 9), taking into account the thermal conductivity and thickness of the snowpack. Therefore, the surface temperature  $T_{\text{ss}}$  ( $^\circ\text{C}$ ) is calculated as a weighted average derived from the distances from the top of the snow cover and the first soil temperature node to the surface and the respective temperatures of air and soil, and thermal conductivities of snow and soil (Granberg et al., 1999):

$$T_{ss} = \frac{T_1 + aT_{av}}{1 + a} \quad (10.5a)$$

where:

$$a = \frac{\lambda_{snow} \left( \frac{\Delta z_1}{2} \right)}{\lambda_1 \Delta z_{snow}} \quad (10.5b)$$

with  $\lambda_1$  ( $J\ cm^{-1}\ ^\circ C^{-1}\ d^{-1}$ ) and  $\Delta z_1$  (cm) are thermal conductivity and thickness of the first soil compartment. Thermal conductivity of the snowpack  $\lambda_{snow}$  ( $J\ cm^{-1}\ ^\circ C^{-1}\ d^{-1}$ ) depends on density  $\rho_{snow}$  ( $kg\ cm^{-3}$ ) of the snowpack (Granberg et al., 1999):

$$\lambda_{snow} = k_{snow} \rho_{snow}^2 \quad (10.6)$$

where  $k_{snow}$  is a thermal conductivity parameter for snow ( $24.71 \cdot 10^8\ J\ cm^5\ kg^{-2}\ ^\circ C^{-1}\ d^{-1}$ ). For  $\rho_{snow}$  the average value of  $170 \cdot 10^{-6}\ kg\ cm^{-3}$  is taken (Granberg et al., 1999), so that  $\lambda_{snow}$  equals  $71.4\ J\ cm^{-1}\ ^\circ C^{-1}\ d^{-1}$  (15% of  $\lambda_{water}$ ).

Thickness of the snowpack  $\Delta z_{snow}$  (cm) is calculated from storage and density of snow, and density of water ( $1000 \cdot 10^{-6}\ kg\ cm^{-3}$ ):

$$\Delta z_{snow} = \frac{\rho_{water}}{\rho_{snow}} S_{snow} = \frac{1000}{170} S_{snow} \quad (10.7)$$

## 10.2 Frost

If the option for frost is activated, SWAP simulates freezing of soil water when soil temperature drops below a threshold value  $T_{frz}$  ( $^\circ C$ ). Soil ice has a sharp impact on water flow and storage in the soil. To simulate this impact in situations where soil ice occurs, some transport parameters are adjusted. This is achieved by using a factor  $f_T(z)$ , which introduces a correction when soil temperatures are below  $T_{frz}$  at depth  $z$ . This correction factor is assumed to be linear related to the fraction of soil ice  $f_{ice}(z)$  (-) at depth  $z$ :

$$f_T(z) = 1 - f_{ice}(z) \quad (10.8)$$

where  $f_{ice}(z)$  is the fraction of the free volumetric soil water content (actual water content minus residual water content) at depth ( $z$ ).

According to measured data from Kujala (1991),  $f_{ice}(z)$  can reasonably well be described by a linear function of soil temperature  $T(z)$  ( $^\circ C$ ) between two threshold temperatures:

$$f_{ice}(z) = 0 \quad \text{for } T(z) \geq T_{frz} \quad (10.9.a)$$

$$f_{ice}(z) = \frac{T_{frz} - T(z)}{T_{frz} - T_{milt}} \quad \text{for } T_{milt} < T(z) < T_{frz} \quad (10.9.b)$$

$$f_{ice}(z) = 1 \quad \text{for } T(z) \leq T_{milt} \quad (10.9.c)$$

where  $T_{frz}$  is the temperature below which soil water starts freezing, and  $T_{milt}$  is the temperature above which soil ice starts melting and below which all soil water except  $\theta_{res}$  is frozen. A value of  $T_{frz} < 0\ ^\circ C$  expresses freezing point depression.  $T_{frz}$  and  $T_{milt}$  are model input with default values of 0 and  $-1\ ^\circ C$ .

The following parameters are adjusted in case of soil ice:

1. hydraulic conductivity  $K$ :

$$K^*(z) = f_T(z)(K(z) - K_{min}) + K_{min} \quad (10.10)$$

where  $K^*(z)$  is the adjusted hydraulic conductivity at depth  $z$  ( $\text{cm d}^{-1}$ ) and  $K_{\min}$  is a very small hydraulic conductivity ( $\text{cm d}^{-1}$ ). For  $K_{\min}$  a default value is taken of  $10^{-10} \text{ cm d}^{-1}$ ;

2. actual crop uptake is reduced as:

$$S_a(z) = \alpha_{\text{rf}} S_a(z) \quad \text{with } \alpha_{\text{rf}} = 0 \quad \text{for } T(z) < 0 \text{ } ^\circ\text{C} \quad (10.11)$$

where  $\alpha_{\text{rf}}$  is a multiplication factor for soil temperatures (-);

3. drainage fluxes of all drainage levels:

$$q_{\text{drain},i}(z) = f_T(z) q_{\text{drain},i}(z) \quad (10.12)$$

where  $q_{\text{drain},i}(z)$  is the drainage flux at depth  $z$  from drainage level  $i$  ( $\text{cm d}^{-1}$ );

4. bottom flux:

$$q_{\text{bot}} = f_T(z) q_{\text{bot}} \quad (10.13)$$

where  $q_{\text{bot}}$  is the flux across the bottom of the modelled soil profile and  $z$  the bottom depth;

5. boundary fluxes (drainage and bottom) when the available air volume is very low:

When drainage does not occur and the available air volume is very low ( $<0.01 \text{ cm cm}^{-3}$ ), the bottom flux is reduced to zero.

When drainage occurs and the available air volume is very low ( $<0.01 \text{ cm cm}^{-3}$ ), the drainage fluxes of frozen soil compartments above the drainage level are reduced to zero.

The (available) air volume in the soil  $V_{\text{air}}$  ( $\text{cm}^3$ ) for a soil profile that becomes saturated equals:

$$V_{\text{air}} = \sum_{i=n}^m \{ (\theta_{s,i} - \theta_i) \Delta z_i \} \quad (10.14)$$

where  $\theta_{s,i}$  is the saturated water content ( $\text{cm}^3 \text{ cm}^{-3}$ ),  $\theta_i$  is the actual water content ( $\text{cm}^3 \text{ cm}^{-3}$ ),  $i$  is a particular node number,  $n$  is the node number of the bottom compartment,  $m$  is the node number of the highest soil compartment with a temperature below  $T_{\text{melt}}$  starting to count from the bottom compartment, and  $\Delta z_i$  is the nodal distance ( $z_i - z_{i+1}$ )

When a soil compartment is frozen ( $T(z) < T_{\text{melt}}$ ) the pore volume of the total soil profile becomes smaller, because only the compartments below this layer are used in the calculation.

An example is a soil in spring that is melting (Figure 10.2). The lower compartments were never frozen and the melting starts at the soil surface. It is possible that the first 4 compartments have melted and only the compartments 5 - 8 are frozen. Now the air volume is only calculated for compartments  $n$  (bottom) to  $m=5$  (frozen). The following is then valid:

- when drainage does not occur and the available air volume is very low ( $<0.01 \text{ cm cm}^{-3}$ ), the bottom flux is reduced to zero;
- when drainage does occur and the available air volume is very low ( $<0.01 \text{ cm cm}^{-3}$ ), the drainage fluxes of all drainage systems, that have a drainage level above the lowest frozen soil compartment, are reduced to zero.

**Figure 10.2** Partly frozen soil profile.

---

## 10.3 User instructions

Obviously the options for snow and frost can only be used when the soil temperature simulation is activated.

For the snow option, the two threshold temperatures  $T_{\text{rain}}$  and  $T_{\text{snow}}$ , the initial storage of snow at the beginning of the simulations  $S_{\text{snow}}$  and the 'degree-day factor'  $a$  are required as model input (Box 10.1).

The frost option requires input for the two threshold temperatures  $T_{\text{frz}}$  and  $T_{\text{mit}}$  (Box 10.1).

### Box 10.1 Input for snow and frost modules in file \*.SWP.

```
*****
* Part 9: Snow and frost
* Snow
  SWSNOW = 0          ! Switch, calculate snow accumulation and melt [Y=1, N=0]
* If SWSNOW = 1, specify:
  SNOWINCO = 22.0     ! Initial snow water equivalent [0..1000 cm, R]
  TEPRRAIN = 2.0      ! Temperature above which all precipitation is rain [ 0..10 °C, R]
  TEPRSNOW = -2.0     ! Temperature below which all precipitation is snow [-10..0 °C, R]
  SNOWCOEF = 0.3      ! Snowmelt calibration factor [0.0...10.0 -, R]
* Frost
  SWFROST = 0 ! Switch, in case of frost reduce soil water flow [Y=1, N=0]
* If SWFROST = 1, specify soil temperature range in which soil water flow is reduced
  TFROSTSTA = 0.0     ! Soil temperature (°C) at which reduction of water fluxes starts [-10..5 °C, R]
  TFROSTEND = -1.0    ! Soil temperature (°C) at which reduction of water fluxes ends [-10..5 °C, R]

# 11 Irrigation

The SWAP agrohydrological simulations are useful to develop optimal irrigation schedules by evaluating various application strategies.

Irrigation strategies may be applied with a fixed or a scheduled regime. The fixed regime is defined by the time and depth of irrigation application (Par. 11.1).

The scheduled regime is defined by different criteria for time and depth of an irrigation application (Par. 11.2). A combination of a fixed and a scheduled regime is also possible. This regime allows the evaluation of water productivity in relation to several degrees of water stress.

Irrigation or flooding may also be simulated using supply of water from a nearby field or from surface waters (Par. 11.3).

This chapter ends with a description of input requirements (Par. 11.4).

## 11.1 Fixed irrigation regime

At user-defined dates a fixed application depth may be applied as an observed gross irrigation dose ( $I_g$ ). Interception of irrigation water may occur, dependent on the type of application (surface irrigation or sprinkling):

$$I_n = I_g - E_i \quad (11.1)$$

where  $I_n$  is the net amount of irrigation water (cm/d),  $I_g$  is the gross given amount of fixed irrigation water (cm/d),  $E_i$  is the amount of intercepted irrigation water (cm/d). The interception irrigation water ( $E_i$ ) is assumed to evaporate at the same day as the irrigation occurs.

## 11.2 Scheduled irrigation regime

A specific combination of timing and depth criteria is valid from a user-defined date in the growing season until the end of crop growth. Both timing and depth criteria may be defined as a function of crop development stage. Scheduled irrigation only occurs when a crop is present.

### 11.2.1 Timing criteria

For the timing of the irrigation schedule one out of five different criteria must be selected:

- *Allowable daily stress*
- *Allowable depletion of readily available water in the root zone*
- *Allowable depletion of totally available water in the root zone*
- *Allowable depletion amount of water in the root zone*
- *Critical pressure head or moisture content at sensor depth*

At the start of each day the selected criterion is evaluated based on state variables at the start of the day. The outcome of this evaluation may generate an irrigation event on that same day.

The five different evaluation criteria are explained in Par. 11.2.1.1 – 11.2.1.5.

In addition the user may prescribe a fixed or a minimum interval between irrigated applications (Par. 11.2.1.6 and 11.2.1.7).

#### 11.2.1.1 Allowable daily stress

The level of soil water shortage by drought and salinity stress may be diagnosed from a threshold defined by the ratio of reduced transpiration  $T_r$  to potential transpiration  $T_p$ . Irrigation is applied whenever reduced transpiration becomes lower than a limit defined by this threshold:

$$T_r \leq f_1 T_p \quad (11.2)$$

where  $T_r$  is the transpiration reduced by drought and salinity stress ( $\text{cm d}^{-1}$ ),  $T_p$  is the potential transpiration ( $\text{cm d}^{-1}$ ),  $f_1$  (-) is a user defined factor for allowable daily stress.

#### 11.2.1.2 Allowable depletion of readily available water

In order to optimize irrigation scheduling where irrigation is always secured before conditions of soil moisture stress occur, the maximum amount of depletion of readily available water in the root zone can be specified. Irrigation is then applied whenever the water depletion exceeds fraction  $f_2$  of the readily available water amount:

$$(U_{\text{field}} - U_a) \geq f_2 (U_{\text{field}} - U_{h3}) \quad (11.3)$$

where  $U_a$  (cm) is the actual water storage in the root zone,  $U_{\text{field}}$  (cm) is the root zone water storage at  $h =$  given value for field capacity, and  $U_{h3}$  (cm) is the root zone water storage at  $h = h_3$ , the pressure head from where root water extraction starts being reduced due to drought stress,  $f_2$  (-) is a user-defined depletion fraction.

$U_a$  is calculated by integrating numerically the water content in the rooting layer. For deficit irrigation purposes, stress can be allowed by specifying  $f_2 > 1$ .

#### 11.2.1.3 Allowable depletion of totally available water

Depletion of water in the root zone can also be evaluated relative to the total amount of water available in the root zone as given by the difference between the field capacity and the wilting point. Irrigation is then applied whenever the depletion of water in the root zone exceeds fraction  $f_3$  (-) of the available water:

$$(U_{\text{field}} - U_a) \geq f_3 (U_{\text{field}} - U_{h4}) \quad (11.4)$$

where  $U_{h4}$  (cm) is the root zone water storage at  $h = h_4$ , the pressure head at which root water extraction is reduced to zero,  $f_3$  (-) is a user-defined factor depletion fraction.

#### 11.2.1.4 Allowable depletion of field capacity water

In case of high-frequency irrigation systems (drip) it may be useful to specify the maximum amount of water that may be extracted below field capacity,  $\Delta U_{\text{max}}$  (cm). Irrigation is then applied if:

$$U_a \leq U_{\text{field}} - \Delta U_{\text{max}} \quad (11.5)$$

#### 11.2.1.5 Critical pressure head or moisture content

The user may specify a soil moisture threshold value  $\theta_{\text{min}}$  ( $\text{cm}^3 \text{cm}^{-3}$ ) or pressure head threshold value  $h_{\text{min}}$  (cm) and a corresponding depth for which the threshold values are valid.

This option may be used to simulate irrigation with automated systems relying on soil moisture measurements. Irrigation is then applied whenever a threshold is exceeded:

$$\theta_{\text{sensor}} \leq \theta_{\text{min}} \quad \text{or} \quad h_{\text{sensor}} \leq h_{\text{min}} \quad (11.6)$$

where  $\theta_{\text{sensor}}$  and  $h_{\text{sensor}}$  are the sensor values for soil moisture and pressure head, which are simulated by SWAP.

In addition the user may specify a salinity threshold value above which over-irrigation is applied to decrease the high salinity concentrations.

#### 11.2.1.6 Fixed interval

By default an irrigation interval has a minimum of one day and the length of the interval is variable and determined by the moment when one of the previously mentioned timing criteria becomes valid.

The user may optionally choose a fixed interval of one week between possible irrigation events.

Irrigation events occur weekly during crop growth when the required amount of water to bring the rootzone to field capacity exceeds a given threshold value. This threshold value is input to the model.

---

### 11.2.1.7 Minimum interval

The length of the interval between irrigation events may also be variable and be determined by the moment when one of the timing criteria becomes valid.

The user may select this option in addition to one of the previous five criteria (Par. 11.2.1.1 - 11.2.1.5) to have a minimum time interval between irrigation applications.

## 11.2.2 Depth criteria

Scheduled irrigation results in gross irrigation depths. Interception of irrigation water may occur in case of sprinkling irrigation:

$$I_n = I_g - E_i \quad (11.7)$$

Two options are available for the amount of irrigation:

- *An amount which increases root zone soil moisture to field capacity*
- *A fixed amount*

The actual amount of the application may be limited to a minimum and a maximum amount. Both criteria are explained in more detail hereafter.

### 11.2.2.1 Back to Field Capacity

The soil water content in the root zone is brought back to field capacity. This option may be useful in case of sprinkler and micro irrigation systems, which allow variation of irrigation application depth. An additional irrigation amount ( $dI$ ) can be defined to leach salts, while the user may define a smaller irrigation amount when rainfall is expected. This amount is added to field capacity when the rain amount is larger than a specified threshold value (see Box 11.4).

### 11.2.2.2 Fixed irrigation depth

A specified amount of water is applied. This option applies to most gravity systems, which allow little variation in irrigation application depth.

### 11.2.2.3 Limited depth

With this option enabled the calculated irrigation depth  $I_g$  will be limited to the range:

$$I_{g,\min} \leq I_g \leq I_{g,\max} \quad (11.8)$$

where  $I_{g,\min}$  and  $I_{g,\max}$  are the specified minimum and maximum irrigation amount values (mm), respectively.

## 11.3 Flooding

Both fixed and scheduled irrigation may result in flooding conditions. Flooding may also be generated by increasing surface water levels or by adding water from a nearby field (runon). The option for input of surface water levels is described in Chapter 5 (Surface water management). The option for runon for nearby fields as input to the model is described in Par. 4.5.1 (Surface Runoff).

## 11.4 User instructions

### 11.4.1 Fixed irrigation regime

Fixed irrigation depths must be entered in the \*.SWP file (Box 11.1).

### Box 11.1 Fixed irrigation in the input file \*.SWP, CROP-Section part 2.

```

```

# 12 Case studies

## 12.1 Hupsel Brook

The Hupsel Brook catchment has been a well-known field site for hydrological studies since the 1960s. It has been used for studies on evapotranspiration (Stricker and Brutsaert, 1978), soil physical properties (Hopmans and Stricker, 1989), relations between flow routes and water quality (Van den Eertwegh, 2002; Rozemeijer et al., 2010; Van der Velde et al., 2012) and rainfall-runoff modelling (Bierkens and Puente, 1990; Brauer et al., 2014). The catchment of 6.5 km<sup>2</sup> is slightly sloping (0.8%). Its soil consists of a loamy sand layer (with some clay, peat and gravel) of 0.2 to 10 m thickness on an impermeable clay layer of more than 20 m thickness (Brauer et al., 2014).

**Figure 12.1** Environmental input data of case 1: typical field in Hupsel Brook catchment.

We selected a typical field in the Hupsel Brook catchment to demonstrate SWAP in- and output files. Figure 12.1 shows the environmental settings. The simulation run covers the period 2002-2004 with 3 crops: maize, potato and grass. Each crop is simulated with a different crop module in SWAP: maize with the simple module for a static crop, potato with the WOFOST module for a dynamic crop, and the specialized WOFOST module for grass growth.

Potential evapotranspiration fluxes are calculated with daily meteorological observations and the Penman-Monteith equation. Also daily values for rainfall are used, as in the catchment with its mild slopes and sandy soils no runoff is expected.

The sandy soil profile consists of a top- and sublayer with thicknesses of 30 and 170 cm, respectively. The soil hydraulic functions are derived from the Staring series (Appendix 7): texture B2 for the top layer and texture O2 for the sublayer.

At the bottom of the soil profile a layer of boulder clay with low permeability prevents vertical soil water movement. Therefore at the bottom a zero flux condition is specified. Drainage fluxes are calculated for subsurface drains at 80 cm depth and with a lateral distance of 11 m.

Initial soil water contents are assumed to be in hydrostatic equilibrium with a groundwater level at 75 cm depth. On 5 January 2002 a tracer is applied, which leaches in the subsequent years towards the drains.

SWAP prints two yearly water balances: a summary (\*.BAL) and an extensive (\*.BLC). Box 12.1 shows an example of the extensive water balance for the year 2002. In this output file the fluxes are presented between the subdomains plant, snow, pond layer, soil, and their environment, as depicted in Figure 12.2. In addition to the in- and outgoing fluxes, of each subdomain also the water storage and balance is depicted. For instance the ponding layer received 80.44 cm rain and 7.79 cm soil water from the first soil compartment. Of this amount 16.09 cm evaporated towards the atmosphere, and 72.64 cm infiltrated into the first soil compartment. As both the initial and final storage of the ponding layer are zero, the storage change is also zero.

**Figure 12.2** Scheme of water fluxes between the subdomains plant, snow, ponding layer, soil and surface water.

Output intervals may range from 0.001 day to 1 year. In this case output is requested at the end of each month (SWMONTH = 1). SWAP prints both incremental and cumulative water balance fluxes. Box 12.2 shows the incremental water fluxes for year 2002. The actual transpiration rates are close to the potential transpiration rates due to the high rain amounts in the summer season and the shallow groundwater levels. In May the maize is not yet covering the soil and the actual soil evaporation rate is substantial: 2.48 cm/month. Drainage mainly occurs in the winter months Jan – Mar and Oct – Dec. In the summer months May and June the soil water storage declines with 1.41 and 3.72 cm, respectively. Due to large rainfall amounts in July, during this month the soil water storage increases with 2.08 cm. At the monthly resolution the simulated groundwater levels fluctuate between -35.6 cm (31 Dec) and -118.64 cm (30 Sep) with respect to soil surface.

On 5 January 2002 a tracer is applied (500 mg/cm<sup>2</sup>). Box 12.3 lists the simulated cumulative solute balance fluxes for the year 2002. After one year, 84.87 mg/cm<sup>2</sup> solutes have leached towards the drains. The remaining amount, 415.1 mg/cm<sup>2</sup> or 83.0 % of the applied dose, is still in the soil profile and groundwater on 31 December 2002.

### Grassland, Yield (kg.ha DM)

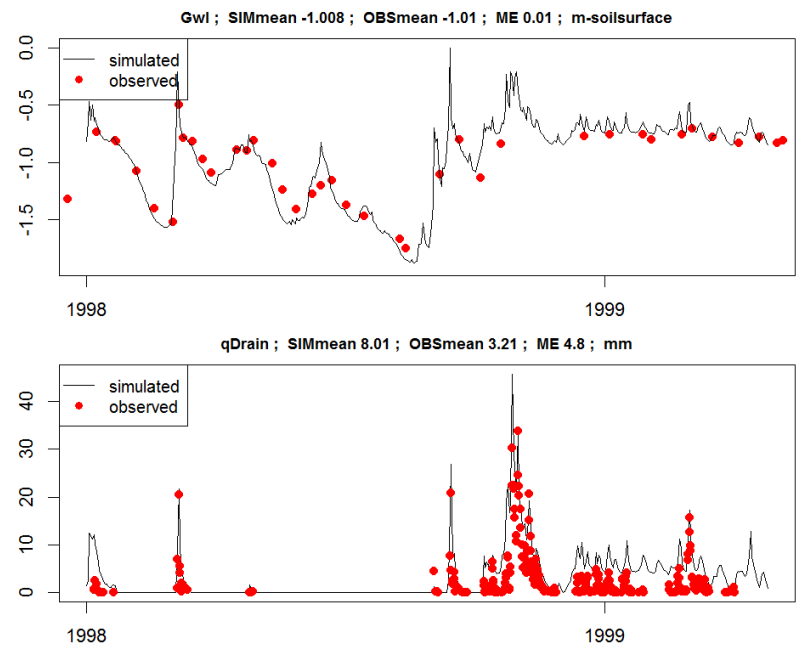

**Figure 12.3** Observed, potential simulated and actual simulated yields ( $\text{kg ha}^{-1}$ ) of a grassland field experiments in Ruurlo (600 kg N, field16-600n-2k-80).

## 12.3 Macropore flow

This case describes a field experiment where macro pore flow is evident; a detailed description of the field experiment has been given by Smelt et al., (2003).

The precipitation excess is discharged from a field with a shallow groundwater level between 0.5 and 1.5 meter below the soil surface. Discharge occurs towards drains was simulated in the framework of pesticide leaching studies (Tiktak et al., 2012a) who also applied the same model tools at a national level (Tiktak et al., 2012b).

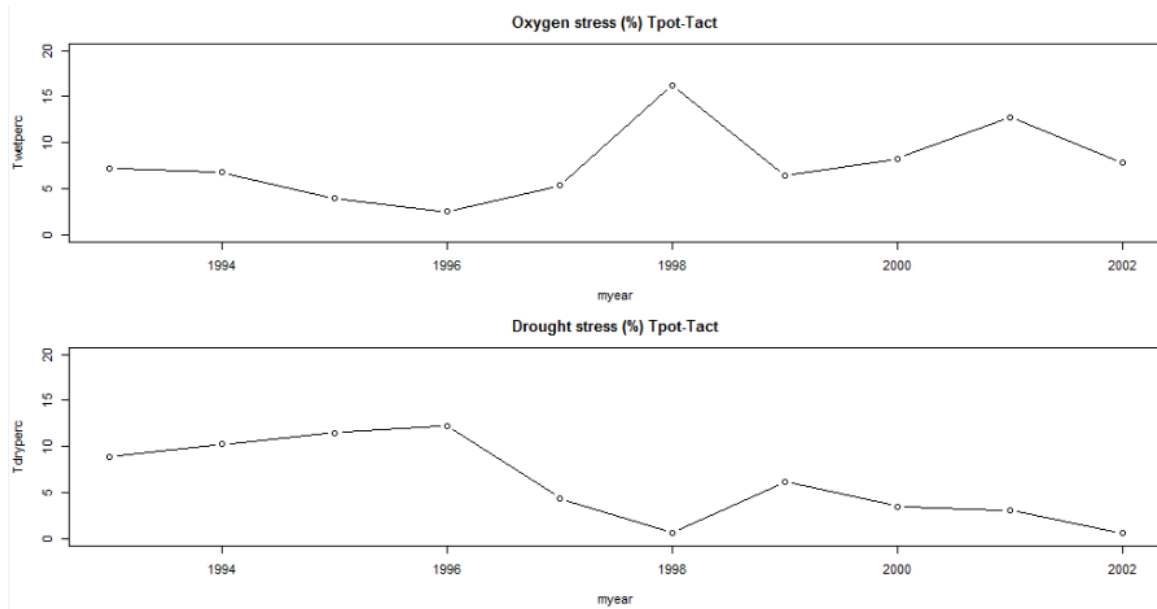

**Figure 12.4** Upper figure: Observed, and simulated groundwater level (m-soil surface) of a field experiments in Andelst; Lower figure: Observed, and simulated drainage discharge (mm/day) of a field experiment in Andelst.

## 12.4 Oxygen stress

This case describes a field experiment where oxygen stress occurs. It is a grassland field with a shallow groundwater level between 0.0 and 0.5 meter below the soil surface. The input parameters are described in paragraph 3.5.3.

Results of the simulation are displayed in Figure 12.5, showing oxygen stress as transpiration reduction occurring especially in the wet year 1998.

**Figure 12.5** Transpiration reduction ( $Tact/(Tpot-Tact)$ ) due to oxygen stress (upper figure) and drought (bottom figure) below a grassland field in The Netherlands.

For more information and a description of oxygen stress simulation in case of climate-adaptive water management, we refer to Bartholomeus et al. (2015).

## 12.5 Salinity stress

Salinization is one of the major threats to agriculture worldwide, and is an increasing problem. In the Netherlands it is expected that salinization of arable land will increase up to 125.000 hectares (Kempeneer et al., 2007).

Since 2012 field trials have been performed at the open-air laboratory of Salt Farm Texel in the Netherlands in order to investigate salt tolerance of different crops ([www.SaltFarmTexel.com](http://www.SaltFarmTexel.com)). Between 2012 and 2015 varieties of potatoes were daily irrigated (drip irrigation) with seven different salt concentrations located in 56 fields (maximum of eight replica's for each salt concentration). During the experiment, soil moisture of the top layer, soil water salinity at different depths and the crop yields were monitored (De Vos et al., 2016).

For this example simulation results of one field with one potato variety are presented. The salinity of the irrigation water during the growing seasons of 2012 until 2015 was set to respectively 1.7, 16, 20 and 12 dS m<sup>-1</sup>. The threshold of salt concentration in soil water after which the root water uptake is declining was set to 0.732 mg cm<sup>-3</sup> and the decline of root water uptake above the threshold was set to 0.0868 cm<sup>3</sup> mg<sup>-1</sup>. Box 12.6 shows the salt stress settings which is part of the \*.CRP input file.

### Box 12.6 Input file for detailed crop growth: salt stress.

```
* Switch salinity stress
SWSALINITY = 1 ! 0 = No salinity stress
               ! 1 = Maas and Hoffman reduction function
               ! 2 = Use osmotic head

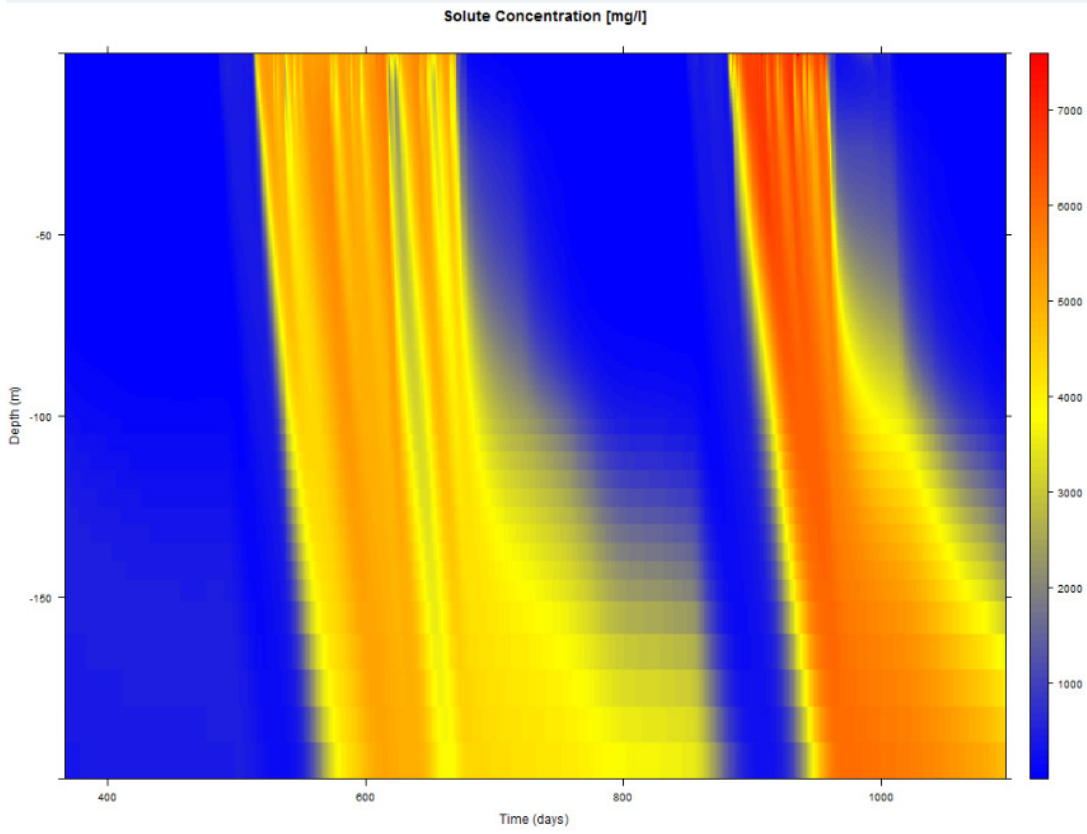

* If SWSALINITY = 1, specify threshold and slope of Maas and Hoffman
SALTMAX   = 0.732 ! Threshold salt concentration in soil water [0..100 mg/cm3, R]
SALTSLOPE = 0.0868 ! Decline of root water uptake above threshold [0..1.0 mg/cm3, R]
```

Meteorological data are gained from an nearby automatic Dutch national weather station De Kooy ([www.knmi.nl](http://www.knmi.nl)). Potato growth parameters are based on standard potatoes for this region (*Solanum Tuberosum* L.) and set similar to the HupselBrook case with a management factor set to 0.8. The settings of the growing season is shown in Table 12.1.

**Table 12.1** Crop rotation scheme of the potato salinity example.

Year	Start	End	Days
2012	17 April	19 July	94
2013	1 May	29 August	121
2014	29 April	12 August	106
2015	7 May	18 August	104

Figure 12.6 shows the simulated salinity of the soil water.

**Figure 12.6** Simulated salinity concentrations in soil water (mg/l).

## 12.6 Surface water

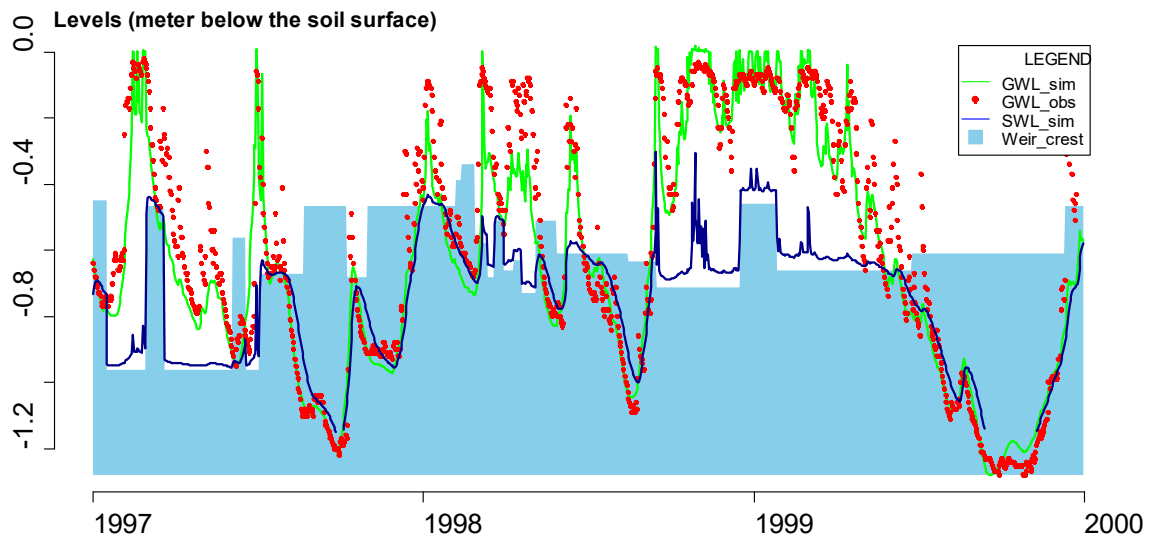

The surface water case is given to explain the capabilities of the SWAP model to simulate the interaction between groundwater and surface water. Many applications of the SWAP model have a focus on the impact of measures in the surface water system on the groundwater and indirectly on the vadose zone. This is driven by the fact that water managers have control over the surface water system. This case illustrates model use to quantify the impact of elevated surface water levels on water and nutrient management of neighboring farmer fields. Input data were derived from the results of a monitoring program, which was carried out in several fields surrounding the "Wildenborch" estate in the eastern part of The Netherlands (Massop et al., 1994). Data series were collected on meteorology, soil, groundwater and surface water during several years. Here we focus on a field with a groundwater observation point (GWL in Figure 12.7) and measurements in the adjacent surface water (SWL and weir in Figure 12.7).

The SWAP model was applied assuming a seepage flux at the lower boundary described as a Cauchy condition due to regional flow and local flow to surface water systems at the lateral boundary. The surface water system was schematized in two systems. The first system has a weir with a movable crest and a depth of 1.0 meter below the soil surface. The second system has a depth of 0.6 meter below the soil surface. The drainage resistances of the two systems were calibrated with PEST (Doherty et al., 1995). The crest level was specified according to monitored data.

**Figure 12.7** Location of monitoring site at the Wildenborch estate where groundwater levels (GWL) and surface water levels (SWL) were measured and controlled by a weir.

The flexible crest level resulted in a dynamic surface water level (Figure 12.8), which follows the monitored levels of the weir crest. Periods of discharge mainly occur in the winter period. Surface water levels drop below the weir crest in dry summer periods, during which groundwater levels also decrease. Groundwater levels, using the calibrated drainage resistances, showed a good agreement between simulated and measures levels (Figure 12.8). The hydrological results were used as input for nutrient studies (Kroes et al., 2002).

**Figure 12.8** Calculated and measured groundwater levels (GWL simulated and GWL observed) and calculated surface water levels (SWL) and controlled by a weir with a variable crest level.

# Appendix 1 Application Penman Monteith method

Description of Penman-Monteith method after Allen et al. (1998).

The original form of the Penman-Monteith equation can be written as (Monteith, 1965, 1981):

$$ET_p = \frac{\frac{\Delta_v}{\lambda_w}(R_n - G) + \frac{p_1 \rho_{air} C_{air}}{\lambda_w} \frac{e_{sat} - e_a}{r_{air}}}{\Delta_v + \gamma_{air} \left(1 + \frac{r_{crop}}{r_{air}}\right)}$$

where  $ET_p$  is the potential transpiration rate of the canopy ( $\text{mm d}^{-1}$ ),  $\Delta_v$  is the slope of the vapour pressure curve ( $\text{kPa } ^\circ\text{C}^{-1}$ ),  $\lambda_w$  is the latent heat of vaporization ( $\text{J kg}^{-1}$ ),  $R_n$  is the net radiation flux at the canopy surface ( $\text{J m}^{-2} \text{d}^{-1}$ ),  $G$  is the soil heat flux ( $\text{J m}^{-2} \text{d}^{-1}$ ),  $p_1$  accounts for unit conversion ( $=86400 \text{ s d}^{-1}$ ),  $\rho_{air}$  is the air density ( $\text{kg m}^{-3}$ ),  $C_{air}$  is the heat capacity of moist air ( $\text{J kg}^{-1} \text{ } ^\circ\text{C}^{-1}$ ),  $e_{sat}$  is the saturation vapour pressure (kPa),  $e_a$  is the actual vapour pressure (kPa),  $\gamma_{air}$  is the psychrometric constant ( $\text{kPa } ^\circ\text{C}^{-1}$ ),  $r_{crop}$  is the crop resistance ( $\text{s m}^{-1}$ ) and  $r_{air}$  is the aerodynamic resistance ( $\text{s m}^{-1}$ ).

To facilitate analysis of the combination equation, an aerodynamic and radiation term are defined:

$$ET_p = ET_{rad} + ET_{aero}$$

where  $ET_p$  is potential transpiration rate of crop canopy ( $\text{cm d}^{-1}$ ),  $ET_{rad}$  is the radiation term ( $\text{cm d}^{-1}$ ) and  $ET_{aero}$  is the aerodynamic term ( $\text{cm d}^{-1}$ ).

The radiation term equals:

$$ET_{rad} = \frac{\Delta_v(R_n - G)}{\lambda_w(\Delta_v + \gamma_{air}^*)}$$

where the modified psychrometric constant ( $\text{kPa } ^\circ\text{C}^{-1}$ ) is:

$$\gamma_{air}^* = \gamma_{air} \left(1 + \frac{r_{crop}}{r_{air}}\right)$$

The aerodynamic term equals:

$$ET_{aero} = \frac{p_1 \rho_{air} C_{air} (e_{sat} - e_a)}{\lambda_w (\Delta_v + \gamma_{air}^*) r_{air}}$$

Many meteorological stations provide mean daily values of air temperature  $T_{air}$  ( $^\circ\text{C}$ ), global solar radiation  $R_s$  ( $\text{J m}^{-2} \text{d}^{-1}$ ), wind speed  $u_0$  ( $\text{m s}^{-1}$ ) and air humidity  $e_{act}$  (kPa). These basic meteorological data are used to apply the Penman Monteith equation.

## Radiation term

The net radiation  $R_n$  ( $\text{J m}^{-2} \text{d}^{-1}$ ) is the difference between incoming and outgoing radiation of both short and long wavelengths. It is the balance between the energy adsorbed, reflected and emitted by the earth's surface:

$$R_n = (1 - \alpha_r) R_s - R_{nl}$$

where  $\alpha_r$  is the reflection coefficient or albedo (-) and  $R_{nl}$  is the net longwave radiation ( $\text{J m}^{-2} \text{d}^{-1}$ ). The albedo is highly variable for different surfaces and for the angle of incidence or slope of the ground surface. It may be as large as 0.95 for freshly fallen snow and as small as 0.05 for a wet bare soil. A green vegetation cover has an albedo of about 0.20-0.25 (De Bruin, 1998). SWAP will assume in case of a crop  $\alpha_r = 0.23$ , in case of bare soil  $\alpha_r = 0.15$ .

The earth emits longwave radiation, which increases with temperature and which is adsorbed by the atmosphere or lost into space. The longwave radiation received by the atmosphere increases its temperature and, as a consequence, the atmosphere radiates energy of its own. Part of this radiation finds its way back to the earth's surface. As the outgoing longwave radiation is almost always greater than the incoming longwave radiation, the net longwave radiation  $R_{nl}$  represents an energy loss. Allen et al. (1998) recommend the following formula for the net longwave radiation:

$$R_{nl} = \sigma_{sb} \left[ \frac{T_{\max}^4 + T_{\min}^4}{2} \right] (0.34 - 0.14 \sqrt{e_{\text{act}}}) (0.1 + 0.9 N_{\text{rel}})$$

where  $\sigma_{sb}$  is the Stefan-Boltzmann constant ( $4.903 \cdot 10^{-3} \text{ J K}^{-4} \text{ m}^{-2} \text{ d}^{-1}$ ),  $T_{\min}$  and  $T_{\max}$  are the minimum and maximum absolute temperatures during the day (K), respectively,  $e_{\text{act}}$  is the actual vapour pressure (kPa), and  $N_{\text{rel}}$  is the relative sunshine duration. The latter can be derived from the measured global solar radiation  $R_s$  and the extraterrestrial radiation  $R_a$  ( $\text{J m}^{-2} \text{d}^{-1}$ ), which is received at the top of the Earth's atmosphere on a horizontal surface:

$$N_{\text{rel}} = \left( \frac{R_s}{R_a} - a \right) \frac{1}{b}$$

where  $a$  and  $b$  are so-called Angstrom coefficients which depend on the local climate. For international use Allen et al. (1998) recommend  $a = 0.25$  and  $b = 0.50$ .

The extraterrestrial radiation  $R_a$  depends on the latitude and the day of the year.  $R_a$  is calculated with:

$$R_a = \frac{G_{\text{sc}}}{\pi} d_r \left[ \omega_s \sin(\varphi) \sin(\delta) + \cos(\varphi) \cos(\delta) \sin(\omega_s) \right]$$

where  $G_{\text{sc}}$  is the amount of solar radiation striking a surface perpendicular to the sun's rays at the top of the Earth's atmosphere, called the solar constant ( $\text{J m}^{-2} \text{d}^{-1}$ ),  $d_r$  is the inverse relative distance Earth-Sun (-),  $\omega_s$  is the sunset hour angle (rad),  $\varphi$  is the latitude (rad) and  $\delta$  is the solar declination (rad). The inverse relative distance Earth-Sun and the solar declination are given by:

$$d_r = 1 + 0.033 \cos\left(\frac{2\pi}{365} J\right)$$

$$\delta = 0.409 \sin\left(\frac{2\pi}{365} J - 1.39\right)$$

where  $J$  is the number of the day in the year (1-365 or 366, starting January 1). The sunset hour angle expresses the day length and is given by:

$$\omega_s = \arccos\left[-\tan(\varphi) \tan(\delta)\right]$$

## Aerodynamic term

Latent heat of vaporization,  $\lambda_w$  (J g<sup>-1</sup>), depends on the air temperature  $T_{air}$  (°C) (Harrison, 1963):

$$\lambda_w = 2501 - 2.361T_{air}$$

Saturation vapour pressure,  $e_{sat}$  (kPa), also can be calculated from air temperature (Tetens, 1930):

$$e_{sat} = 0.611 \exp\left(\frac{17.27 T_{air}}{T_{air} + 237.3}\right)$$

The slope of the vapour pressure curve,  $\Delta_v$  (kPa °C<sup>-1</sup>), is calculated as (Murray, 1967):

$$\Delta_v = \frac{4098 e_{sat}}{(T_{air} + 237.3)^2}$$

The psychrometric constant,  $\gamma_{air}$  (kPa °C<sup>-1</sup>), follows from (Brunt, 1952):

$$\gamma_{air} = 1.63 \frac{p_{air}}{\lambda_w}$$

with  $p_{air}$  the atmospheric pressure (kPa) at elevation  $z_0$  (m), which is calculated from (Burman et al., 1987):

$$p_{air} = 101.3 \left( \frac{T_{air,K} - 0.0065 z_0}{T_{air,K}} \right)^{5.256}$$

Employing the ideal gas law, the atmospheric density,  $\rho_a$  (g cm<sup>-3</sup>), can be shown to depend on  $p$  and the virtual temperature  $T_{vir}$  (K):

$$\rho_{air} = 3.486 \cdot 10^{-3} \frac{p_{air}}{T_{vir}}$$

where the virtual temperature is derived from:

$$T_{vir} = \frac{T_{air,K}}{1 - 0.378 \frac{e_{act}}{p_{air}}}$$

The heat capacity of moist air,  $C_{air}$  (J g<sup>-1</sup> °C<sup>-1</sup>), follows from:

$$C_{air} = 0.622 \frac{\gamma_{air} \lambda_w}{p_{air}}$$

## Aerodynamic resistance

The aerodynamic resistance  $r_{air}$  depends on the wind speed profile and the roughness of the canopy and is calculated as (Allen et al., 1998):

$$r_{air} = \frac{\ln\left(\frac{z_m - d}{z_{om}}\right) \cdot \ln\left(\frac{z_h - d}{z_{oh}}\right)}{\kappa_{vk}^2 \cdot u}$$

where  $z_m$  is height of wind speed measurements (m),  $z_h$  is height of temperature and humidity measurements (m),  $d$  is zero plane displacement of wind profile (m),  $z_{om}$  is roughness parameter for momentum (m) and  $z_{oh}$  is roughness parameter for heat and vapour (m),  $\kappa_{vk}$  is von Karman constant = 0.41 (-),  $u$  is wind speed measurement at height  $z_m$  (m s<sup>-1</sup>).

The parameters  $d$ ,  $z_{om}$  and  $z_{oh}$  are defined as:

$$d = \frac{2}{3} h_{crop}$$

$$z_{om} = 0.123 h_{crop}$$

$$z_{oh} = 0.1 z_{om}$$

with  $h_{crop}$  the crop height (cm)

A default height of 2 m is assumed for wind speed measurements ( $z_m$ ) and height of temperature and humidity measurements ( $z_h$ ).

Meteorological stations generally provide 24 hour averages of wind speed measurements, according to international standards, at an altitude of 10 meter.

To calculate  $r_{air}$ , the average daytime wind (7.00 - 19.00 h) should be used. For ordinary conditions we assume (Smith, 1991) for the average daytime windspeed ( $u_{0,day}$ ):

$$u_{0,day} = 1.33 u_0$$

where  $u_0$  is the measured average wind speed over 24 hours ( $m s^{-1}$ ).

When crop height ( $h_{crop}$ ) reaches below or above measurement height ( $z_{m,meas}$ ), the wind speed is corrected with the following assumptions:

- a uniform wind pattern at an altitude of 100 meter;
- wind speed measurements are carried out above grassland;
- a logarithmic wind profile is assumed;
- below 2 meter wind speed is assumed to be unchanged with respect to a value at an altitude of 2 meter; applying a logarithmic wind profile at low altitudes is not carried out due to the high variation below 2 meter.

These assumptions result in the following equation for wind speed correction:

$$u = \frac{\ln\left(\frac{z_{act} - d_{act}}{z_{om,act}}\right)}{\ln\left(\frac{z_{100} - d_{act}}{z_{om,act}}\right)} \frac{\ln\left(\frac{z_{100} - d_{grass}}{z_{om,grass}}\right)}{\ln\left(\frac{z_{m,meas} - d_{grass}}{z_{om,grass}}\right)} u_{0,day}$$

where:  $u$  wind speed at crop height ( $m s^{-1}$ ),  $z_{act}$  is the actual crop height with a minimum value of 2 m,  $d_{act}$  and  $d_{grass}$  are zero plane displacement of actual crop and grass (m),  $z_{om,act}$  and  $z_{om,grass}$  are roughness parameter for momentum actual crop and grass (m).

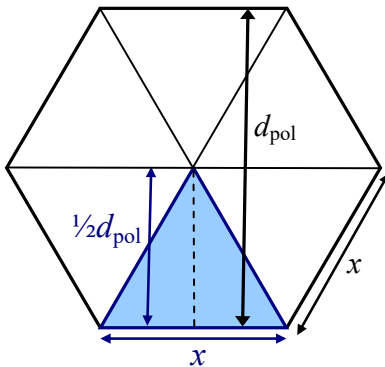

## Appendix 2 Derivation of some macropore geometry equations

Basis of the determination of the effective vertical macropore wall area and the effective crack width is the assumption that the natural variety of soil matrix polygons can be described in terms of one effective regular soil matrix polygon. Crucial condition for this polygon is that many of it should fit together without any gaps to 'tile the plane'. From the regular polygons, only equilateral triangles, squares and regular hexagons have this quality. Empirical experience points out that squares and hexagons in particular are the most likely candidates for these polygons. Which of the two should be chosen, is irrelevant. They are both regular polygons with an even number of sides. All of these even-sided regular polygons, from square to circle, have two relevant, special qualities: the quotient of their perimeter divided by their area is independent of the number of sides and their area is a function of the squared diameter.

### Effective vertical macropore wall area

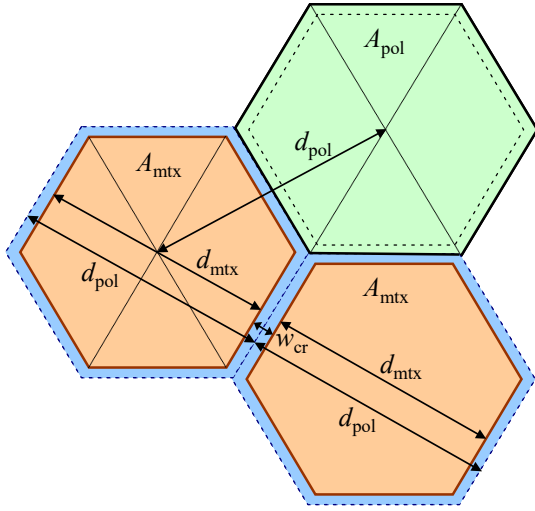

All even-sided regular polygons with  $n$  sides are built up of  $n$  equal isosceles triangles with base of length  $x$  (cm) and height  $\frac{1}{2} d_{\text{pol}}$  (cm) (Figure A2.1). The perimeter of the polygon equals  $n$  times  $x$  and the area equals  $n$  times the area of the triangle. The latter equals  $\frac{1}{4} d_{\text{pol}} x$  (cm<sup>2</sup>), so that:

$$\frac{\text{perimeter}_{\text{pol}}}{\text{area}_{\text{pol}}} = \frac{nx}{n \cdot \frac{1}{4} d_{\text{pol}} x} = \frac{4}{d_{\text{pol}}} \quad (\text{A2.1})$$

**Figure A2.1** Hexagon: 6-sided regular polygon, consists of 6 isosceles triangles with area  $\frac{1}{2}d_{\text{pol}} \cdot \frac{1}{2}x = \frac{1}{4} d_{\text{pol}}x$ . Area of polygon =  $6 \cdot \frac{1}{4} d_{\text{pol}}x$  and perimeter =  $6x$ . Vertical wall area per unit of volume  $A^*_{\text{wall}} = 6x / (6 \cdot \frac{1}{4} d_{\text{pol}}x) = 4 / d_{\text{pol}}$ .

The vertical area of the wall of the polygon of Figure A2.1 per unit of depth is equal to the perimeter of the polygon. In order to express this area per unit of horizontal area it is divided by the area of the polygon. Thus, the effective vertical area of the wall of the matrix polygons  $A^*_{\text{wall}}$  per unit of depth and horizontal area, which implies per unit of volume, equals the quotient of the polygons' perimeter divided by their area, which equals  $4 / d_{\text{pol}}$  (cm<sup>-1</sup>).

**Figure A2.2** Area  $A$  and diameter  $d$  of basis polygon ( $pol$ ) and matrix polygon ( $mtx$ ). Crack width  $w_{cr}$  is equal to the difference between  $d_{pol}$  and  $d_{mtx}$ .

### Effective crack width

For even-sided regular polygons it can be derived that their sides  $x$  (Figure A2.1) can be expressed as  $(C_n / n) d_{pol}$ , where  $C_n$  (-) is a constant that depends on  $n$ . For squares, hexagons and circles,  $C_n$  equals, 4,  $2\sqrt{3}$  and  $n$ , respectively. With  $C_n$  a general equation for the area  $A_{pol}$  ( $cm^2$ ) of an even-sided regular polygon as function of  $d_{pol}^2$  can be derived:

$$A_{pol} = n \frac{1}{4} d_{pol} x = n \frac{1}{4} d_{pol} \frac{C_n}{n} d_{pol} = \frac{1}{4} C_n d_{pol}^2 \quad (A2.2)$$

For this equation, we define  $d_{pol}$  as the distance between the centres of two adjacent basis polygons (Figure A2.2). The value of this diameter is fixed. The value of the actual soil matrix polygon diameter  $d_{mtx}$  depends on the crack width, which is not fixed in case of a shrinking matrix. Thus, the crack width  $w_{cr}$  can be calculated as (Figure A2.2):

$$w_{cr} = d_{pol} - d_{mtx} \quad (A2.3)$$

The horizontal area of the cracks  $A_{cr}$  ( $cm^2$ ) as fraction of  $A_{pol}$  depends on the macropore volume fraction  $V_{mp}$  ( $cm^3 cm^{-3}$ ) as:

$$A_{cr} = V_{mp} A_{pol} \quad (A2.4)$$

The horizontal area of the matrix polygon  $A_{mtx}$  ( $cm^2$ ) is a function of  $d_{mtx}^2$  according to Eq. (A2.2):

$$A_{mtx} = \frac{1}{4} C_n d_{mtx}^2 \quad (A2.5)$$

$A_{mtx}$  is also equal to the difference between basis polygon area  $A_{pol}$  and crack area  $A_{cr}$ :

$$A_{mtx} = A_{pol} - A_{cr} = A_{pol} - V_{mp} A_{pol} = (1 - V_{mp}) A_{pol} = (1 - V_{mp}) \frac{1}{4} C_n d_{pol}^2 \quad (A2.6)$$

Combining the right hands terms of Eq. (A2.5) and Eq. (A2.6) yields:

$$\frac{1}{4} C_n d_{mtx}^2 = (1 - V_{mp}) \frac{1}{4} C_n d_{pol}^2 \quad (A2.7)$$

and:

$$d_{mtx}^2 = (1 - V_{mp}) d_{pol}^2 \quad (A2.8)$$

so that:

$$d_{mtx} = d_{pol} \sqrt{1 - V_{mp}} \quad (A2.9)$$

And finally, the crack width is expressed as:

$$w_{cr} = d_{pol} - d_{mtx} = d_{pol} \left(1 - \sqrt{1 - V_{mp}}\right) \quad (A2.10)$$

Figure A2.3 shows the crack width  $w_{cr}$  as function of the macropore volume fraction  $V_{mp}$  for different polygon diameters  $d_{pol}$ .

**Figure A2.3** Crack width  $w_{cr}$  as function of the macropore volume fraction  $V_{mp}$  for different polygon diameters  $d_{pol}$

#### Effect of crack width $w_{cr}$ on calculation of area of vertical wall $A^*_{wall}$ and distance $x_{pol}$

Strictly speaking, the vertical macropore wall area  $A^*_{wall}$  and the horizontal distance  $x_{pol}$  should be calculated on the basis of  $d_{mtx}$  instead of  $d_{pol}$ . However,  $x_{pol}$  is always used in combination with  $A^*_{wall}$  as:  $A^*_{wall} / x_{pol}$  (Eq. (6.32), Eq. (6.35) and Eq. (6.36)). This quotient is similar for using  $d_{mtx}$  and  $d_{pol}$ :

$$\frac{A^*_{wall,mtx}}{x_{pol,mtx}} = \frac{\frac{4}{d_{mtx}} \frac{A_{mtx}}{A_{pol}}}{\frac{1}{2} d_{mtx}} = \frac{\frac{4}{d_{mtx}} \frac{d_{mtx}^2}{d_{pol}^2}}{\frac{1}{2} d_{mtx}} = \frac{4}{\frac{1}{2} d_{pol}^2} = \frac{A^*_{wall}}{x_{pol}} \quad (A2.11)$$

Only in Eq. (6.29), the calculation of the absorption,  $A^*_{wall}$  is used without dividing by  $x_{pol}$ . In that case,  $A^*_{wall,mtx}$  is used for  $A^*_{wall}$ . Therefore,  $A^*_{wall}$  is corrected with Eq. (A2.9) according to:

$$A^*_{wall,mtx} = \frac{d_{mtx}}{d_{pol}} A^*_{wall} = \frac{d_{pol} \sqrt{1 - V_{mp}}}{d_{pol}} A^*_{wall} = \sqrt{1 - V_{mp}} A^*_{wall} \quad (A2.12)$$

# Appendix 4 Partial derivatives of $F_i$ to pressure heads

The coefficients of the Jacobian are given by:

$$\begin{aligned} \frac{\partial F_i}{\partial h_{i-1}^{j+1,p}} &= -\frac{K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} - \kappa \frac{\partial K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_{i-1}^{j+1,p}} \left( \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + 1 \right) \\ \frac{\partial F_i}{\partial h_i^{j+1,p}} &= \frac{\Delta z_i}{\Delta t^j} C_i^{j+1,p} + \Delta z_i \frac{\partial S_{m,i}^{j+1,p}}{\partial h_i^{j+1,p}} + \frac{K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + \frac{K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} \\ &\quad - \kappa \frac{\partial K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_i^{j+1,p}} \left( \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + 1 \right) + \kappa \frac{\partial K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_i^{j+1,p}} \left( \frac{h_i^{j+1,p} - h_{i+1}^{j+1,p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + 1 \right) \\ \frac{\partial F_i}{\partial h_{i+1}^{j+1,p}} &= -\frac{K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + \kappa \frac{\partial K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_{i+1}^{j+1,p}} \left( \frac{h_i^{j+1,p} - h_{i+1}^{j+1,p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + 1 \right) \end{aligned}$$

Where  $C_i^{j+1,p}$  is the differential moisture capacity ( $\text{cm}^{-1}$ ).  $\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_i^{j+1,p}}$  and  $\frac{\partial K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_i^{j+1,p}}$  are the partial derivatives of the internodal conductivity to the pressure head. The calculation of the partial derivatives for the top and bottom compartment requires special attention.

The Jacobian coefficient for the first compartment reads as:

*Flux controlled top boundary condition*

$$\frac{\partial F_1}{\partial h_1^{j+1}} = \frac{\Delta z_1}{\Delta t^j} C_1^{j+1} + \Delta z_1 \frac{\partial S_{m,1}^{j+1}}{\partial h_1^{j+1}} + \frac{K_{\frac{1}{2}}^{j+\kappa}}{\frac{1}{2}(\Delta z_1 + \Delta z_{i+1})} + \kappa \frac{\partial K_{\frac{1}{2}}^{j+\kappa}}{\partial h_1^{j+1}} \left( \frac{h_1^{j+1} - h_2^{j+1}}{\frac{1}{2}(\Delta z_1 + \Delta z_2)} + 1 \right)$$

*Head controlled top boundary condition*

$$\begin{aligned} \frac{\partial F_1}{\partial h_1^{j+1}} &= \frac{\Delta z_1}{\Delta t^j} C_1^{j+1} + \Delta z_1 \frac{\partial S_{m,1}^{j+1}}{\partial h_1^{j+1}} + \frac{K_{\frac{1}{2}}^{j+1}}{\frac{1}{2}\Delta z_i} + \frac{K_{\frac{1}{2}}^{j+\kappa}}{\frac{1}{2}(\Delta z_1 + \Delta z_{i+1})} \\ &\quad - \frac{\partial K_{\frac{1}{2}}^{j+1}}{\partial h_1^{j+1}} \left( \frac{h_0^{j+1} - h_1^{j+1}}{\frac{1}{2}\Delta z_1} + 1 \right) + \kappa \frac{\partial K_{\frac{1}{2}}^{j+\kappa}}{\partial h_1^{j+1}} \left( \frac{h_1^{j+1} - h_2^{j+1}}{\frac{1}{2}(\Delta z_1 + \Delta z_2)} + 1 \right) \end{aligned}$$

The internodal conductivity  $K_{\frac{1}{2}}^{j+1}$  is irrespective the value of  $\kappa$  always treated implicitly.

The Jacobian coefficient for the last compartment reads as:

*Flux controlled bottom boundary*

$$\frac{\partial F_n}{\partial h_n^{j+1}} = \frac{\Delta z_n}{\Delta t^j} C_n^{j+1} + \Delta z_n \frac{\partial S_{m,n}^{j+1}}{\partial h_n^{j+1}} + \frac{K_{n-\frac{1}{2}}^{j+\kappa}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} - \kappa \frac{\partial K_{n-\frac{1}{2}}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right)$$

*Head controlled bottom boundary*

$$\frac{\partial F_n}{\partial h_n^{j+1,p}} = \frac{\Delta z_n}{\Delta t^j} C_n^{j+1} + \Delta z_n \frac{\partial S_{m,n}^{j+1}}{\partial h_n^{j+1}} + \frac{K_{n-1/2}^{j+\kappa}}{1/2(\Delta z_{n-1} + \Delta z_n)} + \frac{K_{n+1/2}^{j+\kappa}}{1/2\Delta z_n} - \kappa \frac{\partial K_{n-1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{1/2(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + \kappa \frac{\partial K_{n+1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_n^{j+1} - h_{bot}^{j+1}}{1/2\Delta z_n} + 1 \right)$$

*Predefined groundwater levels*

$$\frac{\partial F_i}{\partial h_n^{j+1}} = \frac{\Delta z_i}{\Delta t^j} C_n^{j+1} + \Delta z_n \frac{\partial S_{m,n}^{j+1}}{\partial h_n^{j+1}} + \frac{K_{n-1/2}^{j+\kappa}}{1/2(\Delta z_{n-1} + \Delta z_n)} - \kappa \frac{\partial K_{n-1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{1/2(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + \left( \frac{z_n - z_{n+1}}{z_n - gwI} \right) \frac{K_{n+1/2}^{j+\kappa}}{1/2(\Delta z_n + \Delta z_{n+1})} + \kappa \frac{\partial K_{n+1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \left( \frac{z_n - z_{n+1}}{z_n - gwI} \right) \frac{h_n^{j+1}}{1/2(\Delta z_n + \Delta z_{n+1})} + 1 \right)$$

*Cauchy relation for the bottom boundary*

$$\frac{\partial F_n}{\partial h_n^{j+1,p}} = \frac{\Delta z_n}{\Delta t^j} C_n^{j+1} + \Delta z_n \frac{\partial S_{m,n}^{j+1}}{\partial h_n^{j+1}} + \frac{K_{n-1/2}^{j+\kappa}}{1/2(\Delta z_{n-1} + \Delta z_n)} + \frac{K_{n+1/2}^{j+\kappa}}{1/2\Delta z_n + cK_{n+1/2}^{j+\kappa}} - \kappa \frac{\partial K_{n-1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{1/2(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + \kappa \frac{\partial K_{n+1/2}^{j+\kappa}}{\partial h_n^{j+1}} \frac{1}{2\Delta z_n} \left( \frac{h_n^{j+1} - (\phi - z_n)}{(1/2\Delta z_n + cK_{n+1/2}^{j+\kappa})^2} \right)$$

*Seepage face*

$$h_n^{j+1} + 1/2\Delta z_n < 0 \rightarrow \frac{\partial F_1}{\partial h_1^{j+1}} = \frac{\Delta z_1}{\Delta t^j} C_1^{j+1} + \Delta z_1 \frac{\partial S_{m,1}^{j+1}}{\partial h_1^{j+1}} + \frac{K_{1/2}^{j+\kappa}}{1/2(\Delta z_1 + \Delta z_{i+1})} + \kappa \frac{\partial K_{1/2}^{j+\kappa}}{\partial h_1^{j+1}} \left( \frac{h_1^{j+1} - h_2^{j+1}}{1/2(\Delta z_1 + \Delta z_2)} + 1 \right)$$

$$h_n^{j+1} + 1/2\Delta z_n \not< 0 \rightarrow \frac{\partial F_n}{\partial h_n^{j+1,p}} = \frac{\Delta z_n}{\Delta t^j} C_n^{j+1} + \Delta z_n \frac{\partial S_{m,n}^{j+1}}{\partial h_n^{j+1}} + \frac{K_{n-1/2}^{j+\kappa}}{1/2(\Delta z_{n-1} + \Delta z_n)} + \frac{K_{n+1/2}^{j+\kappa}}{1/2\Delta z_n} - \kappa \frac{\partial K_{n-1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{1/2(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + \kappa \frac{\partial K_{n+1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_n^{j+1}}{1/2\Delta z_n} + 1 \right)$$

*Free drainage*

$$\frac{\partial F_n}{\partial h_n^{j+1,p}} = \frac{\Delta z_n}{\Delta t^j} C_n^{j+1} + \Delta z_n \frac{\partial S_{m,n}^{j+1}}{\partial h_n^{j+1}} + \frac{K_{n-1/2}^{j+\kappa}}{1/2(\Delta z_{n-1} + \Delta z_n)} + \frac{K_{n+1/2}^{j+1}}{1/2\Delta z_n} - \kappa \frac{\partial K_{n-1/2}^{j+\kappa}}{\partial h_n^{j+1}} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{1/2(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + \kappa \frac{\partial K_{n+1/2}^{j+1}}{\partial h_n^{j+1}}$$

The internodal conductivity  $K_{n+1/2}^{j+1}$  is in the case of free drainage irrespective the value of  $\kappa$  always treated implicitly

# Appendix 5 Implicit linearization of hydraulic conductivities

An implicit linearization of hydraulic conductivities in the numerical elaboration of the Richards equation (Appendix 4) requires expressions for the derivative of the conductivity to the pressure head:

Arithmetic mean:

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_{i-1}^{j+1, p}} = \frac{1}{2} \frac{\partial K_{i-1}^{j+1, p}}{\partial h_{i-1}^{j+1, p}}$$

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_i^{j+1, p}} = \frac{1}{2} \frac{\partial K_i^{j+1, p}}{\partial h_i^{j+1, p}}$$

Weighted arithmetic mean:

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_{i-1}^{j+1, p}} = \frac{\Delta z_{i-1}}{\Delta z_{i-1} + \Delta z_i} \frac{\partial K_{i-1}^{j+1, p}}{\partial h_{i-1}^{j+1, p}}$$

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_i^{j+1, p}} = \frac{\Delta z_i}{\Delta z_{i-1} + \Delta z_i} \frac{\partial K_i^{j+1, p}}{\partial h_i^{j+1, p}}$$

Geometric mean:

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_{i-1}^{j+1, p}} = \frac{1}{2} \left( \frac{K_i^{j+1, p}}{K_{i-1}^{j+1, p}} \right)^{\frac{1}{2}} \frac{\partial K_{i-1}^{j+1, p}}{\partial h_{i-1}^{j+1, p}}$$

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_i^{j+1, p}} = \frac{1}{2} \left( \frac{K_{i-1}^{j+1, p}}{K_i^{j+1, p}} \right)^{\frac{1}{2}} \frac{\partial K_i^{j+1, p}}{\partial h_i^{j+1, p}}$$

Weighted geometric mean:

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_{i-1}^{j+1, p}} = \frac{\Delta z_{i-1}}{\Delta z_{i-1} + \Delta z_i} \left( \frac{K_i^{j+1, p}}{K_{i-1}^{j+1, p}} \right)^{\frac{\Delta z_i}{\Delta z_{i-1} + \Delta z_i}} \frac{\partial K_{i-1}^{j+1, p}}{\partial h_{i-1}^{j+1, p}}$$

$$\frac{\partial K_{i-\frac{1}{2}}^{j+\kappa, \kappa p}}{\partial h_i^{j+1, p}} = \frac{\Delta z_i}{\Delta z_{i-1} + \Delta z_i} \left( \frac{K_{i-1}^{j+1, p}}{K_i^{j+1, p}} \right)^{\frac{\Delta z_{i-1}}{\Delta z_{i-1} + \Delta z_i}} \frac{\partial K_i^{j+1, p}}{\partial h_i^{j+1, p}}$$

A relation for the conductivity derivative to the pressure head  $\frac{\partial K}{\partial h}$  is given by:

$$\frac{\partial K}{\partial h} = \frac{\partial K}{\partial S_e} \frac{\partial S_e}{\partial h}$$

Where for the Mualem (1976)  $K(S_e)$  relationship:

$$\frac{\partial K}{\partial S_e} = K_{sat} S_e^{\lambda-1} \left[ 1 - \left( 1 - S_e^{\frac{1}{m}} \right)^m \right] \left[ \lambda + \left( 1 - S_e^{\frac{1}{m}} \right)^{m-1} \left( (2 + \lambda) S_e^{\frac{1}{m}} - \lambda \right) \right]$$

$$\frac{\partial S_e}{\partial h} = \frac{C}{\theta_{sat} - \theta_{res}}$$

The coefficients of the Jacobian are given by:

$$\begin{aligned} \frac{\partial F_i}{\partial h_{i-1}^{j+1,p}} &= -\frac{K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} - \kappa \frac{\partial K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_{i-1}^{j+1,p}} \left( \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + 1 \right) \\ \frac{\partial F_i}{\partial h_i^{j+1,p}} &= \frac{\Delta z_i}{\Delta t^j} C_i^{j+1,p} + \Delta z_i \frac{\partial S_{m,i}^{j+1,p}}{\partial h_i^{j+1,p}} + \frac{K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + \frac{K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} \\ &\quad - \kappa \frac{\partial K_{i-\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_i^{j+1,p}} \left( \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + 1 \right) + \kappa \frac{\partial K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_i^{j+1,p}} \left( \frac{h_i^{j+1,p} - h_{i+1}^{j+1,p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + 1 \right) \\ \frac{\partial F_i}{\partial h_{i+1}^{j+1,p}} &= -\frac{K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + \kappa \frac{\partial K_{i+\frac{1}{2}}^{j+\kappa,\kappa p}}{\partial h_{i+1}^{j+1,p}} \left( \frac{h_i^{j+1,p} - h_{i+1}^{j+1,p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + 1 \right) \end{aligned}$$

# Appendix 6 Numerical solution heat flow equation

The discretized form of the heat flow equation as described in Chapter 9, is:

$$C_i^{j+1/2} (T_i^{j+1} - T_i^j) = \frac{\Delta t^j}{\Delta z_i} \left[ \lambda_{i-1/2}^{j+1/2} \frac{T_{i-1}^{j+1} - T_i^{j+1}}{\Delta z_u} - \lambda_{i+1/2}^{j+1/2} \frac{T_i^{j+1} - T_{i+1}^{j+1}}{\Delta z_\ell} \right] \quad (A6.1)$$

where for notational convenience the subscript heat of thermal conductivity  $\lambda$  and soil heat capacity  $C$  is omitted. Equation [A6.1] can be rewritten as:

$$-\frac{\Delta t^j}{\Delta z_i \Delta z_u} \lambda_{i-1/2}^{j+1/2} T_{i-1}^{j+1} + \left[ C_i^{j+1/2} + \frac{\Delta t^j}{\Delta z_i \Delta z_u} \lambda_{i-1/2}^{j+1/2} + \frac{\Delta t^j}{\Delta z_i \Delta z_\ell} \lambda_{i+1/2}^{j+1/2} \right] T_i^{j+1} - \frac{\Delta t^j}{\Delta z_i \Delta z_\ell} \lambda_{i+1/2}^{j+1/2} T_{i+1}^{j+1} = C_i^{j+1/2} T_i^j \quad (A6.2)$$

Application of Eq. (A6.2) to each node results in a tri-diagonal matrix:

$$\begin{bmatrix} \beta_1 & \gamma_1 & & & & & \\ \alpha_2 & \beta_2 & \gamma_2 & & & & \\ & \alpha_3 & \beta_3 & \gamma_3 & & & \\ & & & & \alpha_{n-1} & \beta_{n-1} & \gamma_{n-1} \\ & & & & \alpha_n & \beta_n & \gamma_n \end{bmatrix} \begin{bmatrix} T_1^{j+1} \\ T_2^{j+1} \\ T_3^{j+1} \\ \vdots \\ T_{n-1}^{j+1} \\ T_n^{j+1} \end{bmatrix} = \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ \vdots \\ f_{n-1} \\ f_n \end{bmatrix} \quad (A6.3)$$

where  $n$  is the number of nodal points. Next the coefficients  $\alpha_i$ ,  $\beta_i$ ,  $\gamma_i$ , and  $f_i$  are explained for the intermediate nodes and for the top and bottom node.

### Intermediate nodes

From Eq. (A6.2) and Eq. (A6.3) we may derive the coefficients:

$$\alpha_i = -\frac{\Delta t^j}{\Delta z_i \Delta z_u} \lambda_{i-1/2}^{j+1/2} \quad (A6.4)$$

$$\beta_i = C_i^{j+1/2} + \frac{\Delta t^j}{\Delta z_i \Delta z_u} \lambda_{i-1/2}^{j+1/2} + \frac{\Delta t^j}{\Delta z_i \Delta z_\ell} \lambda_{i+1/2}^{j+1/2} \quad (A6.5)$$

$$\gamma_i = -\frac{\Delta t^j}{\Delta z_i \Delta z_\ell} \lambda_{i+1/2}^{j+1/2} \quad (A6.6)$$

$$f_i = C_i^{j+1/2} T_i^j \quad (A6.7)$$

### Top node

The temperature at soil surface is set equal to the daily average air temperature,  $T_{\text{avg}}$ . Therefore, in case of the top node, Eq. (A6.1) transforms to:

$$C_1^{j+1/2} (T_1^{j+1} - T_1^j) = \frac{\Delta t^j}{\Delta z_1} \left[ \lambda_{1/2}^{j+1/2} \frac{T_{\text{avg}} - T_1^{j+1}}{\Delta z_u} - \lambda_{1/2}^{j+1/2} \frac{T_1^{j+1} - T_2^{j+1}}{\Delta z_\ell} \right] \quad (\text{A6.8})$$

which can be written as:

$$\left[ C_1^{j+1/2} + \frac{\Delta t^j}{\Delta z_1 \Delta z_u} \lambda_{1/2}^{j+1/2} + \frac{\Delta t^j}{\Delta z_1 \Delta z_\ell} \lambda_{1/2}^{j+1/2} \right] T_1^{j+1} - \frac{\Delta t^j}{\Delta z_1 \Delta z_\ell} \lambda_{1/2}^{j+1/2} T_2^{j+1} = C_1^{j+1/2} T_1^j + \frac{\Delta t^j}{\Delta z_1 \Delta z_u} \lambda_{1/2}^{j+1/2} T_{\text{avg}} \quad (\text{A6.9})$$

Combination of Eq. (A6.9) and (A6.3) gives the following coefficients:

$$\beta_1 = C_1^{j+1/2} + \frac{\Delta t^j}{\Delta z_1 \Delta z_u} \lambda_{1/2}^{j+1/2} + \frac{\Delta t^j}{\Delta z_1 \Delta z_\ell} \lambda_{1/2}^{j+1/2} \quad (\text{A6.10})$$

$$\gamma_1 = - \frac{\Delta t^j}{\Delta z_1 \Delta z_\ell} \lambda_{1/2}^{j+1/2} \quad (\text{A6.11})$$

$$f_1 = C_1^{j+1/2} T_1^j + \frac{\Delta t^j}{\Delta z_1 \Delta z_u} \lambda_{1/2}^{j+1/2} T_{\text{avg}} \quad (\text{A6.12})$$

In case of a snow cover at the soil surface, the average air temperature can no longer be used as a top boundary condition, because of the insulating properties of snow. The corrected top boundary temperature,  $T_{\text{top}}$  ( $^{\circ}\text{C}$ ), is calculated as follows.

$$T_{\text{top}} = \frac{T_{\text{soil}}(1) + a T_{\text{avg}}}{1 + a}$$

$$a = 0.5 \frac{\lambda_{\text{snow}} \Delta z(1)}{\lambda(1) dz_{\text{snow}}} \quad (\text{6.13})$$

$$\lambda_{\text{snow}} = 2.86 \cdot 10^{-6} \times 864 \times R_{\text{snow}}^2$$

$$dz_{\text{snow}} = \frac{s_{\text{snow}}}{0.17}$$

where  $T_{\text{soil}}(1)$  is the current soil temperature of the first soil layer ( $^{\circ}\text{C}$ ),  $T_{\text{avg}}$  is the average air temperature ( $^{\circ}\text{C}$ ),  $\Delta z(1)$  is the thickness of the first soil layer (cm),  $dz_{\text{snow}}$  is the snow layer thickness (cm; see Chapter 10),  $s_{\text{snow}}$  is the amount of snow (equivalent liters of water),  $R_{\text{snow}}$  is the density of snow ( $\text{kg m}^{-3}$ ; Granberg et al., 1999), and  $\lambda_{\text{snow}}$  is the thermal conductivity of snow ( $\text{J cm}^{-1} \text{d}^{-1} \text{ } ^{\circ}\text{C}^{-1}$ ). The expression for  $\lambda_{\text{snow}}$  was taken as one of the possibilities listed in Fukusako (1990; see also Chapter 10). In case  $\lambda(1) < 10^{-10}$ ,  $\lambda(1)$  is set equal to 100.

### Bottom node

SWAP adopts a heat flow rate  $q_{\text{heat,bot}}$  ( $\text{J cm}^{-2} \text{d}^{-1}$ ) at the bottom of the soil profile. At the bottom node, the general heat flow equation, Eq. (A6.1), transforms to:

$$C_n^{j+1/2} (T_n^{j+1} - T_n^j) = \frac{\Delta t^j}{\Delta z_n} \left[ \lambda_{n-1/2}^{j+1/2} \frac{T_{n-1}^{j+1} - T_n^{j+1}}{\Delta z_u} - q_{\text{heat,bot}} \right] \quad (\text{A6.14})$$

which can be written as:

$$-\frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} T_{n-1}^{j+1} + \left[ C_n^{j+1/2} + \frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} \right] T_n^{j+1} = C_n^{j+1/2} T_n^j + \frac{\Delta t^j}{\Delta z_n} q_{\text{heat,bot}} \quad (\text{A6.15})$$

Combination of Eq. (A6.15) and (A6.3) gives the following coefficients:

$$\alpha_n = -\frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} \quad (\text{A6.16})$$

$$\beta_n = C_n^{j+1/2} + \frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} \quad (\text{A6.17})$$

$$f_n = C_n^{j+1/2} T_n^j - \frac{\Delta t^j}{\Delta z_n} q_{\text{heat,bot}} \quad (\text{A6.18})$$

In case of prescribed temperature  $T_{\text{bot}}$  at the soil profile bottom, Eq. (A6.1), transforms to:

$$C_n^{j+1/2} (T_n^{j+1} - T_n^j) = \frac{\Delta t^j}{\Delta z_n} \left[ \lambda_{n-1/2}^{j+1/2} \frac{T_{n-1}^{j+1} - T_n^{j+1}}{\Delta z_u} - \lambda_{n+1/2}^{j+1/2} \frac{T_n^{j+1} - T_{\text{bot}}}{\Delta z_\ell} \right] \quad (\text{A6.19})$$

which can be written as:

$$-\frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} T_{n-1}^{j+1} + \left[ C_n^{j+1/2} + \frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} + \frac{\Delta t^j}{\Delta z_n \Delta z_\ell} \lambda_{n+1/2}^{j+1/2} \right] T_n^{j+1} = C_n^{j+1/2} T_n^j + \frac{\Delta t^j}{\Delta z_n \Delta z_\ell} \lambda_{n+1/2}^{j+1/2} T_{\text{bot}} \quad (\text{A6.20})$$

Combination of Eq. (A6.20) and (A6.3) gives the following coefficients:

$$\alpha_n = -\frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} \quad (\text{A6.21})$$

$$\beta_n = C_n^{j+1/2} + \frac{\Delta t^j}{\Delta z_n \Delta z_u} \lambda_{n-1/2}^{j+1/2} + \frac{\Delta t^j}{\Delta z_n \Delta z_\ell} \lambda_{n+1/2}^{j+1/2} \quad (\text{A6.22})$$

$$f_n = C_n^{j+1/2} T_n^j + \frac{\Delta t^j}{\Delta z_n \Delta z_\ell} \lambda_{n+1/2}^{j+1/2} T_{\text{bot}} \quad (\text{A6.23})$$

<sup>2</sup> These data serve only as a guideline to relative tolerances among crops. Absolute tolerances vary, depending on climate, soil conditions and cultural practices

<sup>3</sup> In gypsiferous soils, plants will tolerate ECe values about 2 dS/m higher than indicated

<sup>4</sup> SALTMAX and SALTSLOPE are values for total salinity in soil water assuming total salinity (mg/cm<sup>3</sup>) = 0.64 x EC (dS/m) (Rhoades et al., (1992)) and EC soil water ≈ 2 EC<sub>e</sub>

<sup>5</sup> Ratings according to Maas (1990): S sensitive, MS moderately sensitive, MT moderately tolerant, and T tolerant

<sup>6</sup> References: 1 Maas and Hoffman (1977), 2 Francois et al. (1986), 3 West and Francois (1982)

<sup>7</sup> Less tolerant during seedling stage, ECe at this stage should not exceed 4 dS/m or 5 dS/m

<sup>8</sup> Sensitive during germination and emergence, ECe should not exceed 3 dS/m

<sup>9</sup> Average of several varieties. Suwannee and Coastal are about 20% more tolerant, and common and Greenfield are about 20% less tolerant than the average

<sup>10</sup> Data from one cultivar, 'Pobred'.

# Appendix 11 Examples of shrinkage characteristics of peat

Shrinkage characteristics of peat and peaty soils (after Hendriks, 2004). Black dots are measurements and lines are fits with Eq. (6.19). Parameter values concern parameters of Eq. (6.19).

Description, organic matter and clay content (mass-%) of the peat soils. Figures in sample codes refer to sample depths in cm.

Sample code	Soil description	Org. matter	Clay
A-15	peaty clay	33	40
A-25	clayey peat	62	21
A-45	sphagnum peat	93	1
D-80	wood peat	81	5
N-80	sphagnum peat	91	2
V-10	peaty, sandy clay	18	17
Z-10	clayey peat	48	36
Z-60	wood peat	82	4
Z-80	wood peat	83	4

## Appendix 12 List of input array lengths

The array lengths of input data are defined as parameters in the Fortran subroutine 'param.fi'. The array lengths can be enlarged by adjusting the values in 'param.fi' en recompilation of the Fortran code. In the internet version SWAP 4 we did define the array lengths as listed in Box 12.1.

Box 12.1 List of standard array lengths in SWAP 4

```
! --- maximum number of years in the simulation period
PARAMETER (MAYRS = 200)
! --- maximum number of crops
PARAMETER (MACROP = 200)
! --- maximum number of compartments
PARAMETER (MACP = 5000)
! --- maximum number of days in the simulation period
PARAMETER (MADAY = MAYRS*366)
! --- maximum number of drainage systems
PARAMETER (MADR = 5)
! --- maximum number of growth stages
PARAMETER (MAGRS = 366)
! --- maximum number of horizons
PARAMETER (MAHO = 1000)
! --- maximum number of time-dependent values for bottom boundary conditions
PARAMETER (MABBC = MADAY)
! --- maximum number of scaling factors
PARAMETER (MASCALE = 100)
! --- maximum number of rainfall records in case of detailed rainfall
PARAMETER (MRAIN = 40000)
! --- maximum number of applied irrigations
PARAMETER (MAIRG = 10000)
! --- maximum number of specified output dates
PARAMETER (MAOUT = 3000)
! --- maximum number of Open Water Levels (basic drainage routine)
PARAMETER (MAOWL = 10*366)
! --- maximum number of soil management events
PARAMETER (MASME = 1000)
! --- maximum number of data pairs in input tables for soil hydraulica relations
PARAMETER (MATAB = 1000)
! --- maximum number of data pairs in input tables for soil hydraulica relations
PARAMETER (MATABENTRIES = 10000)
! --- maximum number of water levels prim. system (ext. dr.)
PARAMETER (MAWLP = 10*366)
! --- maximum number of water levels sec. system (ext. dr.)
PARAMETER (MAWLS = 10*366)
! --- maximum number of surfacewater management periods (ext. dr.)
PARAMETER (MAMP = 10*366)
! --- maximum number of surfacewater management table entries (ext. dr.)
PARAMETER (MAMTE = 25)
! --- maximum number of macropore domains
PARAMETER (MADM = 20)
! --- maximum number of static equilibrium relations
PARAMETER (MASTEQ = 10000)
! --- maximum number of weather records in one year (48 per day)
PARAMETER (NMETFILE = 17568)
```

---

## Appendix 13 List of main SWAP subroutines

Assim	gross CO2 assimilation rate of the crop
Bocodrb	calculate lateral drainage rate and state variables
Bocodre	calculate lateral drainage rate and state variables, including surface water system
Boundbottom	calculate lower boundary conditions
Boundtop	calculate top boundary conditions
CalcGwl	search for groundwater levels
CalcGrid	converts vertical discretization
CropFixed	prescribed crop growth
Drainage	lateral drainage
DeVries	calculate soil thermal properties
DivDra	divide drainage flux to compartments
Fluxes	calculate bottom and compartment fluxes
Grass	detailed grass growth routine
HConduc	calculate hydraulic conductivity from water content
HeadCalc	calculate pressure heads at next time
Hysteresis	check hysteretic reversal and update scanning curve
Integral	integrate intermediate and cumulative water fluxes
Irrigation	initialize and calculate irrigation
MacroPore	calculate crack shrinkage and swelling, including fluxes
MeteoInput	read meteorological data and return values of actual day
MoisCap	calculate moisture capacity from pressure head
NoCrop	specify crop characteristics for bare soil
OutAfo	formatted hydrological output for ANIMO/PESTLA (*.AFO)
OutAun	unformatted hydrological output for ANIMO/PESTLA (*.AUN)
OutBal	write overview balances (*.BAL)
OutBlc	write total water balances (*.BLC)
OutDrf	write drainage fluxes, runoff, etc. (*.DRF)
OutEnd	write final soil state variables for next initial condition
OutInc	write water balance increments (*.INC)
OutSba	write solute balance (*.SBA)
OutSwb	write surface water balance (*.SWB)
OutTem	write soil temperatures (*.TEM)
OutVap	write water and solute profile data (*.VAP)
OutWba	write water balance (*.WBA)
Penmon	calculate potential evaporation and transpiration rates
Ponding	calculation of runoff
PrHead	calculate pressure head from water content
Radiat	calculate fluxes of diffuse and PAR radiation
ReadSwap	read SWAP main input file
ReducEva	calculate actual soil evaporation
RootExtraction	calculate potential and actual water extraction by roots
Snow	snow submodel
SoilWater	calculate soil water rate/state variables
Solute	calculate solute transport
SurfaceWater	calculate rate/state variables of surface water system
Temperature	calculate soil temperatures
TimeControl	handles time variables, switches and flags
Totass	calculate daily total gross assimilation
Warn	output of warnings to screen and log file
WatCon	calculate water content from pressure head
WatStor	calculate water storage in soil profile and cracks
Wofost	detailed crop growth routine
WriteHead	write header with model version, project name, etc.

# Appendix 14 Description of output files \*.afo and \*.aun

This annex describes the content of the output files with extension \*.afo and \*.aun. The content of both files is identical; they only differ in format: one file is binary and unformatted (\*.aun) and the other file is formatted (\*.afo). The description given in this annex uses the following symbols:

- Unit = units as applied in these output files; units differ from those applied in Swap !
- R = data are written to a new record;
- DT = data type; R means Real\*4, I means Integer\*2;
- Mnemonic = the name of the variable as applied in the source code of Swap

Description of variable	Unit	Range	R	DT	Mnemonic
<b>Time domain</b>					
Year when hydrological simulation started	-	[1. .∞>	*	I	bruny
Year when hydrological simulation ended	-	[bruny..∞>	-	I	eruny
Time (Julian daynumber) when hydrological simulation started (Minimum); will be 0.0 when simulation started at 1st of January, 00.00 hour.	-	[0.0..366]	-	R	brund-1
Time (Julian daynumber) when hydrological simulation ended (Maximum)	-	[0.0..366]	-	R	erund
Step size of time-interval for dynamic hydrological data	d	[1.0..30.0]	-	R	period
<b>Geometry of model system</b>					
Number of model compartments	-	[1.numnod]	*	I	numnod
Number of horizons	-	[1 ..numlay	-	I	numlay
Number of drainage systems (value must be 0, 1, 2, 3, 4 or 5)	-	[0,1,2,3,4,5]	-	I	nrlevs
<i>The following 4 variables (botcom – thetawp) are given for the horizons 1 – numlay:</i>					
Compartment number of the deepest compartment (bottom) of each horizon/layer	-	[1..numnod]	*	I	botcom(numlay)
Volume fraction moisture at Saturation	m <sup>3</sup> m <sup>-3</sup>	[0.0 .. 1.0]	*	R	thetas (numlay)
Volume fraction moisture at Field Capacity	m <sup>3</sup> m <sup>-3</sup>	[0.0 .. 1.0]	*	R	thetafc(numlay)
Volume fraction moisture at Wilting point	m <sup>3</sup> m <sup>-3</sup>	[0.0 .. 1.0]	*	R	thetawp(numlay)
<i>The following variable dz is given for the compartments 1 – numnod</i>					
Thickness of compartments	m	[0.001..100]	*	R	dz(numnod)

Description of variable	Unit	Range	R	DT	Mnemonic
<b>Initial conditions</b>					
<i>The following variable theta is given for the compartments 1 – numnod</i>					
Volume fraction moisture inItially present in compartments 1 – NUMNOD	m <sup>3</sup> m <sup>-3</sup>	[0.0 .. 1.0]	*	R	theta(numnod)
InItial groundWATERlevel	m-surface	[0.0..∞>	*	R	gwI
Storage by inItial ponding (m+surface)	m+ surface	[0.0..∞>	-	R	pond
<b>Dynamic part</b>					
Time (Julian daynumber) in hydrological model	-	[0.0..∞>	*	R	tcum
Precipitation ( <b>incl. irrigation</b> ) water flux	m d <sup>-1</sup>	[0.0..∞>	-	R	iprec
Evaporation flux by interception	m d <sup>-1</sup>	[0.0..∞>	-	R	iintc
Actual evaporation flux by bare soil	m d <sup>-1</sup>	[0.0..∞>	-	R	ievap
Evaporation flux by ponding	m d <sup>-1</sup>	[0.0]	-	R	0.0
Potential evaporation flux by soil	m d <sup>-1</sup>	[0.0..∞>	-	R	ipeva
Potential transpiration flux	m d <sup>-1</sup>	[0.0..∞>	-	R	iptra
Flux of surface RUNoff	m d <sup>-1</sup>	[0.0..∞>	-	R	iruno
GroundwATER level at end of time-interval	m-surface	[0.0..∞>	-	R	gwI
Storage by ponding at soil surface at end of time-interval	m+ surface	[0.0..∞>	-	R	pond
<i>The variables h - inqdra are given for the compartments 1 - numnod, with one exception for inq, which is given for the compartments 1 – numnod+1</i>					
Suction (pressure head) of soil moisture (negative when unsaturated)	cm	<-∞..+∞>	*	R	h(numnod)
Volume fraction of moisture at end of time-interval	m <sup>3</sup> m <sup>-3</sup>	[0.0 .. 1.0]	*	R	theta(numnod)
Actual transpiration flux	m d <sup>-1</sup>	[0.0..∞>	*	R	inqrot(numnod)
Flux incoming from above (compartments 1 – numnod+1, downward=positive)	m d <sup>-1</sup>	[0.0..∞>	*	R	inq(numnod+1)
<i>The presence of values for variables inqdra1-inqdra5 is determined by the variable nrlevs. The value of nrlevs determines the number of drainage systems for which flux densities must be given.</i>					
Flux of drainage system of 1st order (e.g. canal)	m d <sup>-1</sup>	[0.0..∞>	*	R	inqdra(1,numnod)
Flux of drainage system of 2nd order (e.g. ditch)	m d <sup>-1</sup>	[0.0..∞>	*	R	inqdra(2,numnod)
Flux of drainage system of 3rd order (e.g. trench)	m d <sup>-1</sup>	[0.0..∞>	*	R	inqdra(3,numnod)
Flux of drainage system of 4th order (e.g. tube drain)	m d <sup>-1</sup>	[0.0..∞>	*	R	inqdra(4,numnod)
Flux of drainage system of 5th order (e.g. rapid drainage)	m d <sup>-1</sup>	[0.0..∞>	*	R	inqdra(5,numnod)

# Appendix 15 Description of output files

## \*.bfo and \*.bun

This annex describes the content of the output files with extension \*.bfo and \*.bun. The content of both files is identical; they only differ in format: one file is binary and unformatted (\*.bun) and the other file is ascii and formatted (\*.bfo). Differences between the (\*.bfo, \*.bun) and (\*.aun, \*.afo, 0) are indicated with a vertical line next to the text.

Part of the content of this file is optional and indicated with grey shading of the corresponding rows. The optional content is indicated with the switch SWOP (see section File Options).

The temperature parameter (Tsoil) has a value of "-99.9" when temperature processes were not simulated.

The snow-parameters (Ssnow, Igsnow, Isubl) have a value of "0", when snow processes were not simulated. This 0-value instead of -99.9-value is applied to facilitate uniformity of water balance calculations.

The description given in these pages uses the following symbols:

- Unit = units as applied in these output files; units mostly differ from those applied in Swap
- Range = upper and lower boundary of given data
- R = an asterisk (\*) indicates that data are written to a new record;
- DT = data type; R means Real\*4, I means Integer\*2, C means CharacterString;
- Mnemonic = the name of the variable as applied in the source code of Swap

Description of variable	Unit	Range	R	DT	Mnemonic
<b>Header of 5 records, each records with a fixed length of 80 characters</b>					
Project Name (example: * Project: CranGras)	-	...	*	C80	Project

# Appendix 17 Numerical scheme soil water boundary conditions

## Top boundary condition

Appropriate criteria for the procedure with respect to the top boundary condition are important for accurate simulation of rapidly changing soil water fluxes near the soil surface. This is for instance the case with infiltration/runoff events during intensive rain showers or when the soil occasionally gets flooded in areas with shallow groundwater tables. At moderate weather and soil wetness conditions the soil top boundary condition will be flux-controlled. In either very wet or very dry conditions the prevailing water pressure head at the soil surface starts to govern the boundary condition.

In case of a *Flux controlled top boundary* the term  $-K_{i-\frac{1}{2}}^{j+\kappa, \kappa p} \left( \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + 1 \right)$  is replaced by the flux through the soil surface  $q_{top}$  ( $\text{cm d}^{-1}$ ) which yields the following expression:

$$F_1 = \frac{\Delta z_1}{\Delta t^j} (\theta_1^{j+1} - \theta_1^j) + q_{top} + K_{\frac{1}{2}}^{j+\kappa} \frac{h_1^{j+1} - h_2^{j+1}}{\frac{1}{2}(\Delta z_1 + \Delta z_2)} + K_{\frac{1}{2}}^{j+\kappa} + \Delta z_1 S_{a,1}^{j+\kappa} + \Delta z_1 S_{d,1}^j + \Delta z_1 S_{m,1}^{j+1}$$

where  $q_{top}$  is calculated from external driving factors as net precipitation ( $q_{prec}$ ), irrigation ( $q_{irri}$ ), melt of a snow pack ( $q_{melt}$ ) runoff originating from adjacent fields ( $q_{runon}$ ) and inundation from adjacent water courses ( $q_{inun}$ )

$$q_{top} = -q_{prec} - q_{irri} - q_{melt} - q_{runon} - q_{inun}$$

In case of a *Head controlled top boundary* the term  $-K_{i-\frac{1}{2}}^{j+\kappa, \kappa p} \left( \frac{h_{i-1}^{j+1,p} - h_i^{j+1,p}}{\frac{1}{2}(\Delta z_{i-1} + \Delta z_i)} + 1 \right)$  is replaced by  $-K_{\frac{1}{2}}^{j+1} \left( \frac{h_0^{j+1} - h_1^{j+1}}{\frac{1}{2}(\Delta z_1)} + 1 \right)$ , where  $h_0^{j+1}$  is the pressure head at the soil surface at the new time level.

The internodal conductivity  $K_{\frac{1}{2}}^{j+1}$  is always treated implicitly.

Within each iteration round and also within each backtracking sub-cycle it is tested whether the combination of  $q_{top}$  and  $h_1^{j+1}$  would lead to  $h_1^{j+1} - \frac{1}{2}(\Delta z_1) \left( \frac{q_{top}}{K_{\frac{1}{2}}^{j+1}} + 1 \right) > 0$ . In such a case it is decided

that the head boundary condition holds and the water balance of the so-called ponding layer is calculated which includes the surface runoff flux and the ponding depth at time level  $j+1$ . The value of  $h_0^{j+1}$  is set to the ponding depth at time level  $j+1$ . The water balance of the ponding layer reads as:

$$\frac{h_0^{j+1} - h_0^j}{\Delta t} = -K_{\frac{1}{2}}^{j+1} \left( \frac{h_0^{j+1} - h_1^{j+1}}{\frac{1}{2}(\Delta z_1)} + 1 \right) + q_{prec} + q_{irri} + q_{melt} + q_{runon} + q_{inun} - q_{e,pond} - q_{runoff} - I_{ru}$$

Where  $I_{ru}$  is the runoff into the macropores (Section 6.1.2).

The surface runoff flux  $q_{runoff}$  is defined as a function of the ponding height:

$$\begin{aligned} h_0^{j+1} \leq h_{0,threshold} & \quad q_{runoff} = 0 \\ h_0^{j+1} > h_{0,threshold} & \quad q_{runoff} = \alpha \left( h_0^{j+1} - h_{0,threshold} \right)^\beta \end{aligned}$$

Where  $\alpha$  and  $\beta$  are coefficients of the surface runoff equation employed by the SWAP model (see Section 4.1). Substitution of surface runoff expression into water balance equation for the ponding layer yields the relation which is solved in the iteration procedure:

$$h_0^{j+1} \left( \frac{1}{\Delta t} + \frac{K_{\frac{1}{2}}^{j+1}}{\frac{1}{2}(\Delta z_1)} \right) + \alpha \left( h_0^{j+1} - h_{0,threshold} \right)^\beta = \frac{h_0^j}{\Delta t} + \frac{K_{\frac{1}{2}}^{j+1}}{\frac{1}{2}(\Delta z_1)} h_1^{j+1} - K_{\frac{1}{2}}^{j+1} + q_{prec} + q_{melt} + q_{runon} - q_{e,pond} - I_{ru}$$

which is solved in the iteration procedure.

### Bottom boundary condition

The SWAP model provides a number of options to describe the relation between saturated shallow soil layers with deep groundwater (see Chapter 5). Beside handling the flux controlled boundary condition and head controlled boundary condition, the model has additional capabilities to combine these basic types of conditions. Additional options comprise the handling of:

- Predefined groundwater levels
- Cauchy relation for the bottom boundary
- Free drainage
- Free outflow

#### Flux controlled bottom boundary

For  $i=n$ , the  $K_{i+\frac{1}{2}}^{j+\kappa, \kappa p} \left( \frac{h_i^{j+1,p} - h_{i+1}^{j+1,p}}{\frac{1}{2}(\Delta z_i + \Delta z_{i+1})} + 1 \right)$ -term in Eq. (2.29) is replaced by  $-q_{bot}$ , which yields:

$$F_n = \frac{\Delta z_n}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right) - q_{bot} + \Delta z_n (S_{a,n}^{j+\kappa} + S_{d,n}^j + S_{m,n}^{j+1})$$

Beside the flux boundary condition, the SWAP model has options to handle groundwater level dependent bottom fluxes. The flux can be formulated as an exponential function of groundwater level, or as the difference between groundwater level and hydraulic head in deep groundwater outside the flow domain divided by a flow resistance. Such a flux is calculated explicitly at the start of the current time step and is treated as a flux condition in the numerical scheme.

#### Head controlled bottom boundary

For  $i=n$ ,  $\Delta z_{i+1}$  is set to zero and  $h_{i+1}^{j+1,p} = h_{bot}$ , which leads to the following expression:

$$F_n = \frac{\Delta z_n}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + K_{n+\frac{1}{2}}^{j+\kappa} \left( \frac{h_n^{j+1} - h_{bot}}{\frac{1}{2}\Delta z_n} + 1 \right) + \Delta z_n (S_{a,n}^{j+\kappa} + S_{d,n}^j + S_{m,n}^{j+1})$$

#### Predefined groundwater levels

First, the lowest partially unsaturated compartment is searched for and is called  $n^*$ . The set of  $n^*$  non-linear equations for  $F(h)$  is then solved for the unsaturated compartments. The bottom boundary condition for this set of equations is defined by:

$$F_{n^*} = \frac{\Delta z_{n^*}}{\Delta t^j} (\theta_{n^*}^{j+1} - \theta_{n^*}^j) - K_{n^*-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n^*-1}^{j+1} - h_{n^*}^{j+1}}{\frac{1}{2}(\Delta z_{n^*-1} + \Delta z_{n^*})} + 1 \right) + K_{n^*+\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n^*}^{j+1} - h_{n^*+1}^{j+1}}{\frac{1}{2}(\Delta z_{n^*} + \Delta z_{n^*+1})} + 1 \right) + \Delta z_{n^*} (S_{a,n^*}^{j+\kappa} + S_{d,n^*}^j + S_{m,n^*}^{j+1})$$

The groundwater level is situated between the nodal points  $n^*$  and  $n^*+1$ . The pressure head of nodal point  $n^*+1$  is approximated  $h_{n^*+1}^{j+1}$  by:

$$h_{n^*+1}^{j+1} = -h_{n^*}^{j+1} \frac{gwl - z_{n^*+1}}{z_{n^*} - gwl}$$

where  $z_{n^*}$  is the height of the node in compartment  $n^*$  and  $gwl$  is the groundwater level. Substitution into Eq. (2.30) yields:

$$F_n^* = \frac{\Delta z_{n^*}}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n^*-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n^*+1}^{j+1} - h_{n^*}^{j+1}}{\frac{1}{2}(\Delta z_{n^*-1} + \Delta z_{n^*})} + 1 \right) + K_{n^*+\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n^*}^{j+1} \left( \frac{z_{n^*} - z_{n^*+1}}{z_{n^*} - gwl} \right)}{\frac{1}{2}(\Delta z_{n^*} + \Delta z_{n^*+1})} + 1 \right) + \Delta z_n (S_{a,n^*}^{j+\kappa} + S_{d,n^*}^j + S_{m,n^*}^{j+1})$$

After iteratively solving the set of equations for  $i \leq n^*$ , the pressure head profile of the compartments  $i > n^*$  can be calculated from the pressure head of the two adjacent upward nodes.

$$h_{i+1}^{j+1} = h_i^{j+1} \left( 1 + \frac{K_{i-\frac{1}{2}}^{j+\kappa} (\Delta z_i + \Delta z_{i+1})}{K_{i+\frac{1}{2}}^{j+\kappa} (\Delta z_{i-1} + \Delta z_i)} \right) - h_{i-1}^{j+1} \frac{K_{i-\frac{1}{2}}^{j+\kappa} (\Delta z_i + \Delta z_{i+1})}{K_{i+\frac{1}{2}}^{j+\kappa} (\Delta z_{i-1} + \Delta z_i)} + \frac{1}{2} (\Delta z_i + \Delta z_{i+1}) \left( 1 - \frac{K_{i-\frac{1}{2}}^{j+\kappa}}{K_{i+\frac{1}{2}}^{j+\kappa}} \right) + \frac{\frac{1}{2} (\Delta z_i + \Delta z_{i+1})}{K_{i+\frac{1}{2}}^{j+\kappa}} \left( \frac{\Delta z_i}{\Delta t^j} (\theta_{sat,i} - \theta_i^j) + \Delta z_i (S_{a,i}^{j+\kappa} + S_{d,i}^j + S_{m,i}^{j+1}) \right)$$

#### Cauchy relation for the bottom boundary

The flux through the bottom boundary is defined by the difference the hydraulic head at the lower boundary and the hydraulic head  $\phi$  (cm) of the regional groundwater specified by the user, divided by a flow resistance  $c$  (d). The hydraulic head at the lower boundary is approximated by the pressure head of the lowest nodal point plus the elevation head of node  $n$ .

$$q_{bot} = \frac{h_n^{j+1} + z_n - \phi}{\frac{\frac{1}{2} \Delta z_n}{K_{n+\frac{1}{2}}^{j+\kappa}} + c}$$

Substitution into Eq. (2.30) yields:

$$F_n = \frac{\Delta z_n}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + K_{n+\frac{1}{2}}^{j+\kappa} \frac{h_n^{j+1} - (\phi - z_n)}{\frac{1}{2} \Delta z_n + c K_{n+\frac{1}{2}}^{j+\kappa}} + \Delta z_n (S_{a,n}^{j+\kappa} + S_{d,n}^j + S_{m,n}^{j+1})$$

#### Seepage face

The seepage face option is used to simulate the soil moisture flow in a lysimeter with an open outlet at the bottom. No outflow occurs when the bottom soil layer is still unsaturated. Since the flow resistance of the outlet is negligible small, no positive pressure head values will be build up at the bottom when the soil water percolates at the bottom. Within the iteration cycle for solving the numerical expression of the Richards equation, it is checked whether the flux or the head controlled boundary condition prevails. When  $h_n^{j+1} + \frac{1}{2} \Delta z_n < 0$  the bottom flux  $q_{bot}$  is set to zero, but when  $h_n^{j+1} + \frac{1}{2} \Delta z_n$  tends to take values larger than zero, the pressure at the bottom is set to zero ( $h_{bot} = 0$ ). The numerical implementation is as follows:

$$h_n^{j+1} + \frac{1}{2} \Delta z_n < 0 \rightarrow F_n = \frac{\Delta z_n}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + \Delta z_n (S_{a,n}^{j+\kappa} + S_{d,n}^j + S_{m,n}^{j+1})$$

$$h_n^{j+1} + \frac{1}{2}\Delta z_n \not\leq 0 \rightarrow F_n = \frac{\Delta z_n}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + K_{n+\frac{1}{2}}^{j+\kappa} \left( \frac{h_n^{j+1}}{\frac{1}{2}\Delta z_n} + 1 \right) + \Delta z_n (S_{a,n}^{j+\kappa} + S_{d,n}^j + S_{m,n}^{j+1})$$

### Free drainage

The free drainage option is applied for soil profiles with deep groundwater levels. The bottom flux is only provoked by gravity flow and the head pressure gradient equals zero:

$$q_{bot} = -K_{n+\frac{1}{2}}^{j+1} \left( \left( \frac{\partial h}{\partial z} \right)_{n+\frac{1}{2}} + 1 \right) \rightarrow q_{bot} = -K_{n+\frac{1}{2}}^{j+1}$$

Substitution into Eq. (2.30) yields:

$$F_n = \frac{\Delta z_n}{\Delta t^j} (\theta_n^{j+1} - \theta_n^j) - K_{n-\frac{1}{2}}^{j+\kappa} \left( \frac{h_{n-1}^{j+1} - h_n^{j+1}}{\frac{1}{2}(\Delta z_{n-1} + \Delta z_n)} + 1 \right) + K_{n+\frac{1}{2}}^{j+1} + \Delta z_n (S_{a,n}^{j+\kappa} + S_{d,n}^j + S_{m,n}^{j+1})$$

Daycrp	day	Day number starting at crop emergence
DVS	-	DeVeLopment Stage
TSUM	grC	Temperature SUM from cropstart
LAIpot	-	Leaf Area Index of crop under potential growth conditions
LAI	-	Leaf Area Index of crop under actual growth conditions
Height	cm	Height of crop under actual growth conditions
CrpFac	-	Crop factor
RootdPot	cm	Rooting depth under potential growth conditions
Rootd	cm	Rooting depth under actual growth conditions
PWLV	kg/ha	Potential dry weight of living plant leaves
WLV	kg/ha	Actual dry weight of living plant leaves
PWST	kg/ha	Potential dry weight of living plant stem
WST	kg/ha	Actual dry weight of living plant stem
PWRT	kg/ha	Potential dry weight of living plant root
WRT	kg/ha	Actual dry weight of living plant root
CPWDM	kg/ha	Cumulative from cropstart potential dry weight of dead and living above ground plant organs
CWDM	kg/ha	Cumulative from cropstart actual dry weight of dead and living above ground plant organs
CPWSO	kg/ha	Cumulative from flowering potential dry weight of living storage organs
CWSO	kg/ha	Cumulative from flowering actual dry weight of s living storage organs (wso)
PGRASSDM	kg/ha	Potential dry weight of dead and living grass
GRASSDM	kg/ha	Actual dry weight of dead and living grass (tagp = wlv+dwlv + wst+dwst)
PMOWDM	kg/ha	Potential amount of harvested grass by mowing
MOWDM	kg/ha	Actual amount of harvested grass by mowing (tagpt = tagpt + (tagp-(wlv+dwlv+wst+dwst)))
PGRAZDM	kg/ha	Potential amount of grazed grass by livestock
GRAZDM	kg/ha	Actual amount of consumed grass by livestock (cuptgraz)
DWLVCROP	kg/ha	Cumulative from cropstart actual dry weight of deceased leafs allocated to soil
DWLVSOL	kg/ha	Cumulative from cropstart actual dry weight of deceased leafs allocated to soil
DWST	kg/ha	Cumulative from cropstart actual dry weight of deceased plant stems
DWRT	kg/ha	Cumulative from cropstart actual dry weight of deceased plant roots
DWSO	kg/ha	Cumulative from cropstart actual dry weight of deceased plant storage organs
HarLosOrm	kg/ha	Harvest losses added to the soil (roots+fr_shoots_fr_stems+fr_stor.organs) at harvest

(HarLosOrm will only be calculated when the C- and N-module for the soil is activated (flCropNut = .true.))

The sum of the above ground biomass should equal the sum of all living and dead (deceased) plant parts, or:  $CWDM = (WLV + WST + WSO) +$

$(DWLVCROP + DWLVSOL + DWST + DWSO)$

The mission of Wageningen University and Research is "To explore the potential of nature to improve the quality of life". Under the banner Wageningen University & Research, Wageningen University and the specialised research institutes of the Wageningen Research Foundation have joined forces in contributing to finding solutions to important questions in the domain of healthy food and living environment. With its roughly 30 branches, 5,000 employees and 10,000 students, Wageningen University & Research is one of the leading organisations in its domain. The unique Wageningen approach lies in its integrated approach to issues and the collaboration between different disciplines.

To explore  
the potential  
of nature to  
improve the  
quality of life
